1 Introduction

1.1 Purpose of this document

This document is a collection of *HOWTOs*. Each *HOWTO* is a short section that demonstrates how to use the containers and operations implemented in the *GenomicRanges* and related packages (*IRanges*, *Biostrings*, *Rsamtools*, *GenomicAlign-*

[ments](#), [BSgenome](#), and [GenomicFeatures](#)) to perform a task typically found in the context of a high throughput sequence analysis.

Unless stated otherwise, the *HOWTOs* are self contained, independent of each other, and can be studied and reproduced in any order.

1.2 Prerequisites and additional recommended reading

We assume the reader has some previous experience with *R* and with basic manipulation of *GRanges*, *GRangesList*, *Rle*, *RleList*, and *DataFrame* objects. See the “An Introduction to Genomic Ranges Classes” vignette located in the [GenomicRanges](#) package (in the same folder as this document) for an introduction to these containers.

Additional recommended readings after this document are the “Software for Computing and Annotating Genomic Ranges” paper [Lawrence et al. (2013)] and the “Counting reads with summarizeOverlaps” vignette located in the [GenomicAlignments](#) package.

To display the list of vignettes available in the [GenomicRanges](#) package, use `browseVignettes("GenomicRanges")`.

1.3 Input data and terminology used across the HOWTOs

In order to avoid repetition, input data, concepts and terms used in more than one *HOWTO* are described here:

- **The [pasillaBamSubset](#) data package:** contains both a BAM file with single-end reads (`untreated1_chr4`) and a BAM file with paired-end reads (`untreated3_chr4`). Each file is a subset of chr4 from the “Pasilla” experiment.

```
> library(pasillaBamSubset)
> untreated1_chr4()
[1] "E:/biocbld/bbs-2.14-bioc/R/library/pasillaBamSubset/extdata/untreated1_chr4.bam"
> untreated3_chr4()
[1] "E:/biocbld/bbs-2.14-bioc/R/library/pasillaBamSubset/extdata/untreated3_chr4.bam"
See ?pasillaBamSubset for more information.
> ?pasillaBamSubset
```
- **Gene models and TranscriptDb objects:** A *gene model* is essentially a set of annotations that describes the genomic locations of the known genes, transcripts, exons, and CDS, for a given organism. In *Bioconductor* it is typically represented as a *TranscriptDb* object but also sometimes as a *GRanges* or *GRangesList* object. The [GenomicFeatures](#) package contains tools for making and manipulating *TranscriptDb* objects.

2 HOWTOs

2.1 How to read single-end reads from a BAM file

As sample data we use the [pasillaBamSubset](#) data package described in the introduction.

```
> library(pasillaBamSubset)
> un1 <- untreated1_chr4() # single-end reads
```

Several functions are available for reading BAM files into *R*:

```
readGAlignments()
readGAlignmentPairs()
readGAlignmentsList()
scanBam()
```

`scanBam` is a low-level function that returns a list of lists and is not discussed further here. See `?scanBam` in the [Rsamtools](#) package for more information.

Single-end reads can be loaded with the `readGAlignments` function from the [GenomicAlignments](#) package.

```
> library(GenomicAlignments)
> gal <- readGAlignments(un1)
```

Data subsets can be specified by genomic position, field names, or flag criteria in the `ScanBamParam`. Here we input records that overlap position 1 to 5000 on the negative strand with `flag` and `cigar` as metadata columns.

```
> what <- c("flag", "cigar")
> which <- GRanges("chr4", IRanges(1, 5000))
> flag <- scanBamFlag(isMinusStrand = TRUE)
> param <- ScanBamParam(which=which, what=what, flag=flag)
> neg <- readGAlignments(un1, param=param)
> neg
```

GAlignments with 37 alignments and 2 metadata columns:

	seqnames	strand	cigar	qwidth	start	end
	<Rle>	<Rle>	<character>	<integer>	<integer>	<integer>
[1]	chr4	-	75M	75	892	966
[2]	chr4	-	75M	75	919	993
[3]	chr4	-	75M	75	967	1041
...
[35]	chr4	-	75M	75	4997	5071
[36]	chr4	-	75M	75	4998	5072
[37]	chr4	-	75M	75	4999	5073

	width	njunc	flag	cigar
	<integer>	<integer>	<integer>	<character>
[1]	75	0	16	75M
[2]	75	0	16	75M
[3]	75	0	16	75M
...
[35]	75	0	16	75M
[36]	75	0	16	75M
[37]	75	0	16	75M

seqlengths:

chr2L	chr2R	chr3L	chr3R	chr4	chrM	chrX	chrYHet
23011544	21146708	24543557	27905053	1351857	19517	22422827	347038

Another approach to subsetting the data is to use `filterBam`. This function creates a new BAM file of records passing user-defined criteria. See `?filterBam` in the [Rsamtools](#) package for more information.

2.2 How to read paired-end reads from a BAM file

As sample data we use the [pasillaBamSubset](#) data package described in the introduction.

```
> library(pasillaBamSubset)
> un3 <- untreated3_chr4() # paired-end reads
```

Paired-end reads can be loaded with the `readGAlignmentPairs` or `readGAlignmentsList` function from the [GenomicAlignments](#) package. These functions use the same mate paring algorithm but output different objects.

Let's start with `readGAlignmentPairs`:

```
> un3 <- untreated3_chr4()
> gapairs <- readGAlignmentPairs(un3)
```

The `GAlignmentPairs` class holds only pairs; reads with no mate or with ambiguous pairing are discarded. Each list element holds exactly 2 records (a mated pair). Records can be accessed as the `first` and `last` segments in a template or as `left` and `right` alignments. See `?GAlignmentPairs` in the [GenomicAlignments](#) package for more information.

```
> gapairs
```

`GAlignmentPairs` with 75346 alignment pairs and 0 metadata columns:

	seqnames	strand	:	ranges	--	ranges
	<Rle>	<Rle>	:	<IRanges>	--	<IRanges>
[1]	chr4	+	:	[169, 205]	--	[326, 362]
[2]	chr4	+	:	[943, 979]	--	[1086, 1122]
[3]	chr4	+	:	[944, 980]	--	[1119, 1155]
...
[75344]	chr4	+	:	[1348217, 1348253]	--	[1348215, 1348251]
[75345]	chr4	+	:	[1349196, 1349232]	--	[1349326, 1349362]
[75346]	chr4	+	:	[1349708, 1349744]	--	[1349838, 1349874]

```
---
seqlengths:
```

chr2L	chr2R	chr3L	chr3R	chr4	chrM	chrX	chrYHet
23011544	21146708	24543557	27905053	1351857	19517	22422827	347038

For `readGAlignmentsList`, mate pairing is performed when `asMates` is set to `TRUE` on the `BamFile` object, otherwise records are treated as single-end.

```
> galist <- readGAlignmentsList(BamFile(un3, asMates=TRUE))
```

`GAlignmentsList` is a more general 'list-like' structure that holds mate pairs as well as non-mates (i.e., singletons, records with unmapped mates etc.) A `mates` metadata column (accessed with `mcols`) indicates which records were paired and is set on both the individual `GAlignments` and the outer list elements.

```
> galist
```

`GAlignmentsList` of length 96632:

```
[[1]]
```

`GAlignments` with 2 alignments and 0 metadata columns:

	seqnames	strand	cigar	qwidth	start	end	width	njunc
[1]	chr4	+	37M	37	169	205	37	0
[2]	chr4	-	37M	37	326	362	37	0

```
[[2]]
```

`GAlignments` with 2 alignments and 0 metadata columns:

	seqnames	strand	cigar	qwidth	start	end	width	njunc
[1]	chr4	+	37M	37	946	982	37	0
[2]	chr4	-	37M	37	986	1022	37	0

```
[[3]]
```

`GAlignments` with 2 alignments and 0 metadata columns:

	seqnames	strand	cigar	qwidth	start	end	width	njunc
[1]	chr4	+	37M	37	943	979	37	0
[2]	chr4	-	37M	37	1086	1122	37	0

```
...
```

```
<96629 more elements>
```

```
---
```

```
seqlengths:
```

chr2L	chr2R	chr3L	chr3R	chr4	chrM	chrX	chrYHet
23011544	21146708	24543557	27905053	1351857	19517	22422827	347038

Non-mated reads are returned as groups by QNAME and contain any number of records. Here the non-mate groups range in size from 1 to 9.

```
> non_mates <- galist[unlist(mcols(galist)$mates) == FALSE]
> table(elementLengths(non_mates))
< table of extent 0 >
```

2.3 How to read and process a big BAM file by chunks in order to reduce memory usage

A large BAM file can be iterated through in chunks by setting a `yieldSize` on the *BamFile* object. As sample data we use the [pasillaBamSubset](#) data package described in the introduction.

```
> library(pasillaBamSubset)
> un1 <- untreated1_chr4()
> bf <- BamFile(un1, yieldSize=100000)
```

Iteration through a BAM file requires that the file be opened, repeatedly queried inside a loop, then closed. Repeated calls to `readGAlignments` without opening the file first result in the same 100000 records returned each time.

```
> open(bf)
> cvg <- NULL
> repeat {
+   chunk <- readGAlignments(bf)
+   if (length(chunk) == 0L)
+     break
+   chunk_cvg <- coverage(chunk)
+   if (is.null(cvg)) {
+     cvg <- chunk_cvg
+   } else {
+     cvg <- cvg + chunk_cvg
+   }
+ }
> close(bf)
> cvg

...
<3 more elements>
```

2.4 How to compute read coverage

The “read coverage” is the number of reads that cover a given genomic position. Computing the read coverage generally consists in computing the coverage at each position in the genome. This can be done with the `coverage()` function.

As sample data we use the [pasillaBamSubset](#) data package described in the introduction.

```
> library(pasillaBamSubset)
> un1 <- untreated1_chr4() # single-end reads
> library(GenomicAlignments)
> reads1 <- readGAlignments(un1)
> cvg1 <- coverage(reads1)
> cvg1

  Lengths: 891 27 5 12 13 45 ... 106 75 1600 75 1659
  Values : 0 1 2 3 4 5 ... 0 1 0 1 0

...
<3 more elements>

Coverage on chr4:
> cvg1$chr4
```

```
integer-Rle of length 1351857 with 122061 runs
  Lengths:  891   27    5   12   13   45 ...  106   75 1600   75 1659
  Values  :    0    1    2    3    4    5 ...    0    1    0    1    0
```

Average and max coverage:

```
> mean(cvg1$chr4)
```

```
[1] 11.33746
```

```
> max(cvg1$chr4)
```

```
[1] 5627
```

Note that `coverage()` is a generic function with methods for different types of objects. See `?coverage` for more information.

2.5 How to find peaks in read coverage

ChIP-Seq analysis usually involves finding peaks in read coverage. This process is sometimes called “peak calling” or “peak detection”. Here we’re only showing a naive way to find peaks in the object returned by the `coverage()` function. *Bioconductor* packages *BayesPeak*, *bumphunter*, *Starr*, *CexoR*, *exomePeak*, *RIPSeeker*, and others, provide sophisticated peak calling tools for ChIP-Seq, RIP-Seq, and other kind of high throughput sequencing data.

Let’s assume `cvg1` is the object returned by `coverage()` (see previous *HOWTO* for how to compute it). We can use the `slice()` function to find the genomic regions where the coverage is greater or equal to a given threshold.

```
> chr4_peaks <- slice(cvg1$chr4, lower=500)
```

```
> chr4_peaks
```

[33]     503     502     501   51881   15116    2020     500     502
[41]   67010   40496
```

2.6 How to retrieve a gene model from the UCSC genome browser

See introduction for a quick description of what *gene models* and *TranscriptDb* objects are. We can use the `makeTranscriptDbFromUCSC()` function from the *GenomicFeatures* package to import a UCSC genome browser track as a *TranscriptDb* object.

```
> library(GenomicFeatures)
> ### Internet connection required! Can take several minutes...
> txdb <- makeTranscriptDbFromUCSC(genome="sacCer2", tablename="ensGene")
```

See `?makeTranscriptDbFromUCSC` in the *GenomicFeatures* package for more information.

Note that some of the most frequently used gene models are available as *TxDb* packages. A *TxDb* package consists of a pre-made *TranscriptDb* object wrapped into an annotation data package. Go to http://bioconductor.org/packages/release/BiocViews.html#___TranscriptDb to browse the list of available *TxDb* packages.

```
> library(TxDb.Hsapiens.UCSC.hg19.knownGene)
> txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene
> txdb
```

TranscriptDb object:

```
| Db type: TranscriptDb
| Supporting package: GenomicFeatures
| Data source: UCSC
| Genome: hg19
| Organism: Homo sapiens
| UCSC Table: knownGene
| Resource URL: http://genome.ucsc.edu/
| Type of Gene ID: Entrez Gene ID
| Full dataset: yes
| miRBase build ID: GRCh37
| transcript_nrow: 82960
| exon_nrow: 289969
| cds_nrow: 237533
| Db created by: GenomicFeatures package from Bioconductor
| Creation time: 2014-03-17 16:15:59 -0700 (Mon, 17 Mar 2014)
| GenomicFeatures version at creation time: 1.15.11
| RSQLite version at creation time: 0.11.4
| DBSCHEMAVERSION: 1.0
```

Extract the transcript coordinates from this gene model:

```
> transcripts(txdb)
```

GRanges with 82960 ranges and 2 metadata columns:

```
seqnames      ranges strand | tx_id
```

```

```

2.7 How to retrieve a gene model from Ensembl

See introduction for a quick description of what *gene models* and *TranscriptDb* objects are. We can use the `makeTranscriptDbFromBiomart()` function from the [GenomicFeatures](#) package to retrieve a gene model from the Ensembl Mart.

```

> library(GenomicFeatures)
> ### Internet connection required! Can take several minutes...
> txdb <- makeTranscriptDbFromBiomart(biomart="ensembl",
+                                   dataset="hsapiens_gene_ensembl")

```

See `?makeTranscriptDbFromBiomart` in the [GenomicFeatures](#) package for more information.

Note that some of the most frequently used gene models are available as TxDb packages. A TxDb package consists of a pre-made *TranscriptDb* object wrapped into an annotation data package. Go to http://bioconductor.org/packages/release/BiocViews.html#___TranscriptDb to browse the list of available TxDb packages.

```

> library(TxDb.Athaliana.BioMart.plantmart21)
> txdb <- TxDb.Athaliana.BioMart.plantmart21
> txdb

2.8 How to load a gene model from a GFF or GTF file

See introduction for a quick description of what *gene models* and *TranscriptDb* objects are. We can use the `makeTranscriptDbFromGFF()` function from the [GenomicFeatures](#) package to import a GFF or GTF file as a *TranscriptDb* object.

```
> library(GenomicFeatures)
> gff_file <- system.file("extdata", "a.gff3", package="GenomicFeatures")
> txdb <- makeTranscriptDbFromGFF(gff_file, format="gff3")
> txdb
```

TranscriptDb object:

```
| Db type: TranscriptDb
| Supporting package: GenomicFeatures
| Data source: E:/biocbld/bbs-2.14-bioc/R/library/GenomicFeatures/extdata/a.gff3
| Organism: NA
| miRBase build ID: NA
| transcript_nrow: 488
| exon_nrow: 1268
| cds_nrow: 1258
| Db created by: GenomicFeatures package from Bioconductor
| Creation time: 2014-08-01 19:55:27 -0700 (Fri, 01 Aug 2014)
| GenomicFeatures version at creation time: 1.16.2
| RSQLite version at creation time: 0.11.4
| DBSCHEMAVERSION: 1.0
```

See `?makeTranscriptDbFromGFF` in the [GenomicFeatures](#) package for more information.

Extract the exon coordinates grouped by gene from this gene model:

2.9 How to retrieve a gene model from AnnotationHub

When a gene model is not available as a *GRanges* or *GRangesList* object or as a *Bioconductor* data package, it may be available on [AnnotationHub](#). In this *HOWTO*, will look for a gene model for *Drosophila melanogaster* on [AnnotationHub](#). Create a 'hub' and filter on *Drosophila melanogaster*:

```
> library(AnnotationHub)
> ### Internet connection required!
> hub <- AnnotationHub()
```

```
> filters(hub) <- list(Species="Drosophila melanogaster")
```

There are 87 files that match *Drosophila melanogaster*.

```
> length(hub)
```

```
[1] 101
```

```
> head(names(hub))
```

```
[1] "ensembl.release.69.fasta.drosophila_melanogaster.cdna.Drosophila_melanogaster.BDGP5.69.cdna.all.fa.rz"
[2] "ensembl.release.69.fasta.drosophila_melanogaster.dna.Drosophila_melanogaster.BDGP5.69.dna.toplevel.fa"
[3] "ensembl.release.69.fasta.drosophila_melanogaster.dna.Drosophila_melanogaster.BDGP5.69.dna_rm.toplevel"
[4] "ensembl.release.69.fasta.drosophila_melanogaster.dna.Drosophila_melanogaster.BDGP5.69.dna_sm.toplevel"
[5] "ensembl.release.69.fasta.drosophila_melanogaster.ncrna.Drosophila_melanogaster.BDGP5.69.ncrna.fa.rz"
[6] "ensembl.release.69.fasta.drosophila_melanogaster.pep.Drosophila_melanogaster.BDGP5.69.pep.all.fa.rz"
```

Retrieve a dm3 file as a *GRanges*.

```
> gr <- hub$goldenpath.dm3.database.ensGene_0.0.1.RData
```

```
> summary(gr)
```

Length	Class	Mode
23017	GRanges	S4

The metadata fields contain the details of file origin and content.

```
> names(metadata(gr)[[2]])
```

[1] "BiocVersion"	"DataProvider"	"Description"	"Genome"
[5] "Tags"	"SourceUrl"	"SourceVersion"	"Species"
[9] "RDataPath"	"RDataName"		

```
> metadata(gr)[[2]]$Tags
```

CharacterList of length 1

```
[[ "7161" ]] ensGene UCSC track Gene Transcript Annotation
```

Split the *GRanges* object by gene name to get a *GRangesList* object of transcript ranges grouped by gene.

```
> txbygn <- split(gr, gr$name)
```

You can now use *txbygn* with the *summarizeOverlaps* function to prepare a table of read counts for RNA-Seq differential gene expression.

Note that before passing *txbygn* to *summarizeOverlaps*, you should confirm that the *seqlevels* (chromosome names) in it match those in the BAM file. See *?renameSeqlevels*, *?keepSeqlevels* and *?seqlevels* for examples of renaming *seqlevels*.

2.10 How to annotate peaks in read coverage

[coming soon...]

2.11 How to prepare a table of read counts for RNA-Seq differential gene expression

Methods for RNA-Seq gene expression analysis generally require a table of counts that summarize the number of reads that overlap or 'hit' a particular gene. In this *HOWTO* we count with the *summarizeOverlaps* function from the *GenomicAlignments* package and create a count table from the results.

Other packages that provide read counting are *Rsubread* and *easyRNASeq*. The *parathyroidSE* package vignette contains a workflow on counting and other common operations required for differential expression analysis.

As sample data we use the [pasillaBamSubset](#) data package described in the introduction.

```
> library(pasillaBamSubset)
> un1 <- untreated1_chr4() # single-end reads
```

`summarizeOverlaps` requires the name of a BAM file(s) and a *gene model* to count against. See introduction for a quick description of what a *gene models* is. The gene model must match the genome build the reads in the BAM file were aligned to. For the *pasilla* data this is *dm3 Dmelanogaster* which is available as a *Bioconductor* package. Load the package and extract the exon ranges grouped by gene:

```
> library(TxDb.Dmelanogaster.UCSC.dm3.ensGene)
> exbygene <- exonsBy(TxDb.Dmelanogaster.UCSC.dm3.ensGene, "gene")
```

`exbygene` is a *GRangesList* object with one list element per gene in the gene model.

`summarizeOverlaps` automatically sets a `yieldSize` on large BAM files and iterates over them in chunks. When reading paired-end data set the `singleEnd` argument to `FALSE`. See `?summarizeOverlaps` for details regarding the count modes and additional arguments.

```
> library(GenomicAlignments)
> se <- summarizeOverlaps(exbygene, un1, mode="IntersectionNotEmpty")
```

The return object is a *SummarizedExperiment* with counts in the assays slot.

```
> class(se)
[1] "SummarizedExperiment"
attr(,"package")
[1] "GenomicRanges"
> head(table(assays(se)$counts))
      0      1      2      3      4      5
15593    1      3      1      4      1
```

The count vector is the same length as `exbygene`:

```
> identical(length(exbygene), length(assays(se)$counts))
[1] TRUE
```

A copy of `exbygene` is stored in the `rowData` slot:

```
> rowData(se)
GRangesList of length 15682:

```

Two popular packages for RNA-Seq differential gene expression are *DESeq* and *edgeR*. Tables of counts per gene are required for both and can be easily created with a vector of counts. Here we use the counts from our *SummarizedExperiment* object:

```
> library(DESeq)
> deseq <- newCountDataSet(assays(se)$counts, rownames(colData(se)))
> library(edgeR)
> edger <- DGEList(assays(se)$counts, group=rownames(colData(se)))
```

2.12 How to summarize junctions from a BAM file containing RNA-Seq reads

As sample data we use the *pasillaBamSubset* data package described in the introduction.

```
> library(pasillaBamSubset)
> un1 <- untreated1_chr4() # single-end reads
> library(GenomicAlignments)
> reads1 <- readGAlignments(un1)
> reads1
```

GAlignments with 204355 alignments and 0 metadata columns:

	seqnames	strand	cigar	qwidth	start	end
	<Rle>	<Rle>	<character>	<integer>	<integer>	<integer>
[1]	chr4	-	75M	75	892	966
[2]	chr4	-	75M	75	919	993
[3]	chr4	+	75M	75	924	998
...
[204353]	chr4	+	75M	75	1348268	1348342
[204354]	chr4	-	75M	75	1348449	1348523
[204355]	chr4	-	75M	75	1350124	1350198

	width	njunc
	<integer>	<integer>
[1]	75	0
[2]	75	0
[3]	75	0
...
[204353]	75	0
[204354]	75	0
[204355]	75	0

```
---
seqlengths:
  chr2L      chr2R      chr3L      chr3R      chr4      chrM      chrX      chrYHet
  23011544  21146708  24543557  27905053  1351857   19517   22422827  347038
```

For each alignment, the aligner generated a CIGAR string that describes its "geometry", that is, the locations of insertions, deletions and junctions in the alignment. See the SAM Spec available on the SAMtools website for the details (<http://samtools.sourceforge.net/>).

The `summarizeJunctions()` function from the *GenomicAlignments* package can be used to summarize the junctions in `reads1`.

```
> junc_summary <- summarizeJunctions(reads1)
> junc_summary
```

GRanges with 910 ranges and 3 metadata columns:

See ?summarizeJunctions in the [GenomicAlignments](#) package for more information.

2.13 How to get the exon and intron sequences of a given gene

The exon and intron sequences of a gene are essentially the DNA sequences of the introns and exons of all known transcripts of the gene. The first task is to identify all transcripts associated with the gene of interest. Our sample gene is the human TRAK2 which is involved in regulation of endosome-to-lysosome trafficking of membrane cargo. The Entrez gene id is '66008'.

```
> trak2 <- "66008"
```

The [TxDb.Hsapiens.UCSC.hg19.knownGene](#) data package contains the gene model corresponding to the UCSC 'Known Genes' track.

```
> library(TxDb.Hsapiens.UCSC.hg19.knownGene)
> txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene
```

The transcript ranges for all the genes in the gene model can be extracted with the `transcriptsBy` function from the [GenomicFeatures](#) package. They will be returned in a named *GRangesList* object containing all the transcripts grouped by gene. In order to keep only the transcripts of the TRAK2 gene we will subset the *GRangesList* object using the `[]` operator.

```
> library(GenomicFeatures)
> trak2_txs <- transcriptsBy(txdb, by="gene")[[trak2]]
> trak2_txs
```

GRanges with 2 ranges and 2 metadata columns:

	seqnames <Rle>	ranges <IRanges>	strand <Rle>	tx_id <integer>	tx_name <character>
[1]	chr2	[202241930, 202316319]	-	12552	uc002uyb.4

```
[2] chr2 [202259851, 202316319] - | 12553 uc002uyc.2
---
seqlengths:
      chr1      chr2 ... chrUn_gl000249
      249250621 243199373 ... 38502
```

`trak2_txs` is a *GRanges* object with one range per transcript in the TRAK2 gene. The transcript names are stored in the `tx_name` metadata column. We will need them to subset the extracted intron and exon regions:

```
> trak2_tx_names <- mcols(trak2_txs)$tx_name
> trak2_tx_names

[1] "uc002uyb.4" "uc002uyc.2"
```

The exon and intron genomic ranges for all the transcripts in the gene model can be extracted with the `exonsBy` and `intronsByTranscript` functions, respectively. Both functions return a *GRangesList* object. Then we keep only the exon and intron for the transcripts of the TRAK2 gene by subsetting each *GRangesList* object by the TRAK2 transcript names.

Extract the exon regions:

```
> trak2_exbytx <- exonsBy(txdb, "tx", use.names=TRUE)[trak2_tx_names]
> elementLengths(trak2_exbytx)

uc002uyb.4 uc002uyc.2
      16      8
```

... and the intron regions:

```
> trak2_inbytx <- intronsByTranscript(txdb, use.names=TRUE)[trak2_tx_names]
> elementLengths(trak2_inbytx)

uc002uyb.4 uc002uyc.2
      15      7
```

Next we want the DNA sequences for these exons and introns. The `getSeq` function from the *Biostrings* package can be used to query a *BSgenome* object with a set of genomic ranges and retrieve the corresponding DNA sequences.

```
> library(BSgenome.Hsapiens.UCSC.hg19)
```

Extract the exon sequences:

```
> trak2_ex_seqs <- getSeq(Hsapiens, trak2_exbytx)
> trak2_ex_seqs

2.14 How to get the CDS and UTR sequences of genes associated with colorectal cancer

In this *HOWTO* we extract the CDS and UTR sequences of genes involved in colorectal cancer. The workflow extends the ideas presented in the previous *HOWTO* and suggests an approach for identifying disease-related genes.

2.14.1 Build a gene list

We start with a list of gene or transcript ids. If you do not have pre-defined list one can be created with the [KEGG.db](#) and [KEGGgraph](#) packages. Updates to the data in the [KEGG.db](#) package are no longer available, however, the resource is still useful for identifying pathway names and ids.

Create a table of KEGG pathways and ids and search on the term 'cancer'.

```
> library(KEGG.db)
> pathways <- toTable(KEGGPATHNAME2ID)
> pathways[grepl("cancer", pathways$path_name, fixed=TRUE),]
```

	path_id	path_name
299	05200	Pathways in cancer
300	05210	Colorectal cancer
302	05212	Pancreatic cancer
303	05213	Endometrial cancer
305	05215	Prostate cancer
306	05216	Thyroid cancer
309	05219	Bladder cancer
312	05222	Small cell lung cancer
313	05223	Non-small cell lung cancer

Use the "05210" id to query the KEGG web resource (accesses the currently maintained data).

```
> library(KEGGgraph)
> dest <- tempfile()
> retrieveKGML("05200", "hsa", dest, "internal")
```

The suffix of the KEGG id is the Entrez gene id. The `translateKEGGID2GeneID` simply removes the prefix leaving just the Entrez gene ids.

```
> crids <- as.character(parseKGML2DataFrame(dest)[,1])
> crgenes <- unique(translateKEGGID2GeneID(crids))
> head(crgenes)

[1] "1630" "836" "842" "1499" "51384" "54361"
```

2.14.2 Identify genomic coordinates

The list of gene ids is used to extract genomic positions of the regions of interest. The Known Gene table from UCSC will be the annotation and is available as a *Bioconductor* package.

```
> library(TxDb.Hsapiens.UCSC.hg19.knownGene)
> txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene
```

If an annotation is not available as a *Bioconductor* annotation package it may be available in [AnnotationHub](#). Additionally, there are functions in [GenomicFeatures](#) which can retrieve data from UCSC and Ensembl to create a TranscriptDb. See `?makeTranscriptDbFromUCSC` for more information.

As in the previous *HOWTO* we need to identify the transcripts corresponding to each gene. The transcript id (or name) is used to isolate the UTR and coding regions of interest. This grouping of transcript by gene is also used to re-group the final sequence results.

The `transcriptsBy` function outputs both the gene and transcript identifiers which we use to create a map between the two. The map is a `CharacterList` with gene ids as names and transcript ids as the list elements.

```
> txbygene <- transcriptsBy(txdb, "gene")[crgenes] ## subset on colorectal genes
> map <- relist(unlist(txbygene, use.names=FALSE)$tx_id, txbygene)
> map
```

```

```

Extract the UTR and coding regions.

```

> cds <- cdsBy(txdb, "tx")
> threeUTR <- threeUTRsByTranscript(txdb)
> fiveUTR <- fiveUTRsByTranscript(txdb)

```

Coding and UTR regions may not be present for all transcripts specified in map. Consequently, the subset results will not be the same length. This length discrepancy must be taken into account when re-listing the final results by gene.

```

> txid <- unlist(map, use.names=FALSE)
> cds <- cds[names(cds) %in% txid]
> threeUTR <- threeUTR[names(threeUTR) %in% txid]
> fiveUTR <- fiveUTR[names(fiveUTR) %in% txid]

```

Note the different lengths of the subset regions.

```

> length(txid) ## all possible transcripts
[1] 1045
> length(cds)
[1] 960
> length(threeUTR)
[1] 919
> length(fiveUTR)
[1] 947

```

These objects are GRangesLists with the transcript id as the outer list element.

```
> cds
```

2.14.3 Extract sequences from BSgenome

The BSgenome packages contain complete genome sequences for a given organism.

Load the BSgenome package for homo sapiens.

```
> library(BSgenome.Hsapiens.UCSC.hg19)
> genome <- BSgenome.Hsapiens.UCSC.hg19
```

Use extractTranscriptSeqs to extract the UTR and coding regions from the BSgenome. This function retrieves the sequences for an any GRanges or GRangesList (i.e., not just transcripts like the name implies).

```
> threeUTR_seqs <- extractTranscriptSeqs(genome, threeUTR)
> fiveUTR_seqs <- extractTranscriptSeqs(genome, fiveUTR)
> cds_seqs <- extractTranscriptSeqs(genome, cds)
```

The return values are DNAStringSet objects.

```
> cds_seqs
```

```

A DNAStringSet instance of length 960
      width seq                      names
[1]  1119 ATGTTGGATGGCCTTGA...TGGCTGGACCAAACCTGA 2043
[2]   900 ATGCGTTTCAGTGGGCGAG...TGGCTGGACCAAACCTGA 2044
[3]  1176 ATGCTGAGACCGGGTGGT...TGGCTGGACCAAACCTGA 2045
...    ...
[958]  681 ATGTTACGACAAGATTCC...CACAAATGAATCAACGTAG 78103
[959]  768 ATGAGTGGAAGGTGACC...CACAAATGAATCAACGTAG 78104
[960]  600 ATGAGTGGAAGGTGACC...CACAAATGAATCAACGTAG 78105

```

Our final step is to collect the coding and UTR regions (currently organized by transcript) into groups by gene id. The `relist` function groups the sequences of a `DNAStringSet` object into a `DNAStringSetList` object, based on the specified `skeleton` argument. The `skeleton` must be a list-like object and only its shape (i.e. its element lengths) matters (its exact content is ignored). A simple form of `skeleton` is to use a partitioning object that we make by specifying the size of each partition. The partitioning objects are different for each type of region because not all transcripts had a coding or 3' or 5' UTR region defined.

```

> lst3 <- relist(threeUTR_seqs, PartitioningByWidth(sum(map %in% names(threeUTR))))
> lst5 <- relist(fiveUTR_seqs, PartitioningByWidth(sum(map %in% names(fiveUTR))))
> lstc <- relist(cds_seqs, PartitioningByWidth(sum(map %in% names(cds))))

```

There are 239 genes in `map` each of which have 1 or more transcripts. The table of element lengths shows how many genes have each number of transcripts. For example, 47 genes have 1 transcript, 48 genes have 2 etc.

```

> length(map)
[1] 239

> table(elementLengths(map))
 1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19 21 30
47 48 46 22 17 18 10  4  3  3  5  3  1  1  1  1  4  1  2  1  1

```

The lists of DNA sequences all have the same length as `map` but one or more of the element lengths may be zero. This would indicate that data were not available for that gene. The tables below show that there was at least 1 coding region available for all genes (i.e., none of the element lengths are 0). However, both the 3' and 5' UTR results have element lengths of 0 which indicates no UTR data were available for that gene.

```

> table(elementLengths(lstc))
 1  2  3  4  5  6  7  8  9 10 11 12 14 15 16 17 18 30
48 54 49 20 17 16  8  5  5  3  1  2  3  1  2  1  3  1

> table(elementLengths(lst3))
 0  1  2  3  4  5  6  7  8  9 11 12 13 14 15 16 17 18 30
 2 49 56 47 19 18 13  9  5  8  2  2  2  1  1  2  1  1  1

> names(lst3)[elementLengths(lst3) == 0L] ## genes with no 3' UTR data
[1] "2255" "8823"

> table(elementLengths(lst5))
 0  1  2  3  4  5  6  7  8  9 10 11 12 14 15 16 17 18 30
 3 48 52 49 19 17 16  8  5  5  3  2  2  3  1  1  1  3  1

> names(lst5)[elementLengths(lst5) == 0L] ## genes with no 5' UTR data
[1] "2255" "27006" "8823"

```

2.15 How to create DNA consensus sequences for read group ‘families’

The motivation for this *HOWTO* comes from a study which explored the dynamics of point mutations. The mutations of interest exist with a range of frequencies in the control group (e.g., 0.1% - 50%). PCR and sequencing error rates make it difficult to identify low frequency events (e.g., < 20%).

When a library is prepared with Nextera, random fragments are generated followed by a few rounds of PCR. When the genome is large enough, reads aligning to the same start position are likely descendant from the same template fragment and should have identical sequences.

The goal is to eliminate noise by grouping the reads by common start position and discarding those that do not exceed a certain threshold within each family. A new consensus sequence will be created for each read group family.

2.15.1 Sort reads into groups by start position

Load the BAM file into a GAlignments object.

```
> library(Rsamtools)
> bamfile <- system.file("extdata", "ex1.bam", package="Rsamtools")
> param <- ScanBamParam(what=c("seq", "qual"))
> library(GenomicAlignments)
> gal <- readGAlignments(bamfile, use.names=TRUE, param=param)
```

Use the sequenceLayer function to lay the query sequences and quality strings on the reference.

```
> qseq <- setNames(mcols(gal)$seq, names(gal))
> qual <- setNames(mcols(gal)$qual, names(gal))
> qseq_on_ref <- sequenceLayer(qseq, cigar(gal),
+                             from="query", to="reference")
> qual_on_ref <- sequenceLayer(qual, cigar(gal),
+                             from="query", to="reference")
```

Split by chromosome.

```
> qseq_on_ref_by_chrom <- splitAsList(qseq_on_ref, seqnames(gal))
> qual_on_ref_by_chrom <- splitAsList(qual_on_ref, seqnames(gal))
> pos_by_chrom <- splitAsList(start(gal), seqnames(gal))
```

For each chromosome generate one GRanges object that contains unique alignment start positions and attach 3 metadata columns to it: the number of reads, the query sequences, and the quality strings.

```
> gr_by_chrom <- lapply(seqlevels(gal),
+   function(seqname)
+   {
+     qseq_on_ref2 <- qseq_on_ref_by_chrom[[seqname]]
+     qual_on_ref2 <- qual_on_ref_by_chrom[[seqname]]
+     pos2 <- pos_by_chrom[[seqname]]
+     qseq_on_ref_per_pos <- split(qseq_on_ref2, pos2)
+     qual_on_ref_per_pos <- split(qual_on_ref2, pos2)
+     nread <- elementLengths(qseq_on_ref_per_pos)
+     gr_mcols <- DataFrame(nread=unname(nread),
+                           qseq_on_ref=unname(qseq_on_ref_per_pos),
+                           qual_on_ref=unname(qual_on_ref_per_pos))
+     gr <- GRanges(Rle(seqname, nrow(gr_mcols)),
+                   IRanges(as.integer(names(nread)), width=1))
+     mcols(gr) <- gr_mcols
+     seqlevels(gr) <- seqlevels(gal)
```

	A BStringSet instance of length 3271	
	width seq	names
[1]	36 <<<<<<<<<<<<<<<<<<<<<5<<<<<;<;7	B7_591:4:96:693:509
[2]	35 <<<<<<<<<0<<<<655<<7<<<:9<<3/:<6):	EAS54_65:7:152:36...
[3]	35 <<<<<<<<<<7;71<<;<;<7;<<3);3*8/5	EAS51_64:8:5:734:57
...	
[3269]	35 <<<<, &<7<<<<<<<<<<<<<<<<<<<<<<<	EAS139_11:7:50:12...
[3270]	35 + ' ' /<<<<7:<;+<;::<<<<;<<<<<<<<<<<	EAS54_65:3:320:20...
[3271]	35 3,,==6==<====<;=====	EAS114_26:7:37:79...

2 reads align to start position 13. Let's have a close look at their sequences:

```
> mcols(gr)$qseq_on_ref[[6]]
```

```
A DNAStringSet instance of length 2
  width seq                      names
[1]   35 ATTGTAATGTGTGGTTAACTCGTCCCTGGCCCA EAS56_61:6:18:467...
[2]   36 ATTGTAATGTGTGGTTAACTCGTCCATGGCCCAG EAS114_28:5:296:3...
```

and their qualities:

```
> mcols(gr)$qual_on_ref[[6]]
```

```

A BStringSet instance of length 2
  width seq
[1] 35 <<<<<<<<;<<<8<<<<<;8;.;6/686&;(16666 EAS56_61:6:18:467...
[2] 36 <<<<<;<<<;<;<<<<<<<<<<<<8<8<3<8;<;<0; EAS114_28:5:296:3...
```

Note that the sequence and quality strings are those projected to the reference so the first letter in those strings are on top of start position 13, the 2nd letter on top of position 14, etc...

2.15.2 Remove low frequency reads

For each start position, remove reads with and under-represented sequence (e.g. threshold = 20% for the data used here which is low coverage). A unique number is assigned to each unique sequence. This will make future calculations easier and a little bit faster.

```
> qseq_on_ref <- mcols(gr)$qseq_on_ref
> tmp <- unlist(qseq_on_ref, use.names=FALSE)
> qseq_on_ref_id <- relist(match(tmp, tmp), qseq_on_ref)
```

Quick look at 'qseq_on_ref_id': It's an IntegerList object with the same length and "shape" as 'qseq_on_ref'.

```
> qseq_on_ref_id
```

IntegerList of length 1934

```
[[1]] 1
[[2]] 2
[[3]] 3
[[4]] 4
[[5]] 5
[[6]] 6 7
[[7]] 8
[[8]] 9
[[9]] 10 11
[[10]] 12
```

```
...
<1924 more elements>
```

Remove the under represented ids from each list element of 'qseq_on_ref_id':

```
> qseq_on_ref_id2 <- endoapply(qseq_on_ref_id,
+   function(ids) ids[countMatches(ids, ids) >= 0.2 * length(ids)])
```

Remove corresponding sequences from 'qseq_on_ref':

```
> tmp <- unlist(qseq_on_ref_id2, use.names=FALSE)
> qseq_on_ref2 <- relist(unlist(qseq_on_ref, use.names=FALSE)[tmp],
+   qseq_on_ref_id2)
```

2.15.3 Create a consensus sequence for each read group family

Compute 1 consensus matrix per chromosome:

```
> split_factor <- rep.int(seqnames(gr), elementLengths(qseq_on_ref2))
> qseq_on_ref2 <- unlist(qseq_on_ref2, use.names=FALSE)
> qseq_on_ref2_by_chrom <- splitAsList(qseq_on_ref2, split_factor)
> qseq_pos_by_chrom <- splitAsList(start(gr), split_factor)
> cm_by_chrom <- lapply(names(qseq_pos_by_chrom),
+   function(seqname)
+     consensusMatrix(qseq_on_ref2_by_chrom[[seqname]],
+       as.prob=TRUE,
+       shift=qseq_pos_by_chrom[[seqname]]-1,
+       width=seqlengths(gr)[[seqname]]))
> names(cm_by_chrom) <- names(qseq_pos_by_chrom)
```

'cm_by_chrom' is a list of consensus matrices. Each matrix has 17 rows (1 per letter in the DNA alphabet) and 1 column per chromosome position.

```
> lapply(cm_by_chrom, dim)
```

```
$seq1
[1] 18 1575
```

```
$seq2
[1] 18 1584
```

Compute the consensus string from each consensus matrix. We'll put "+" in the strings wherever there is no coverage for that position, and "N" where there is coverage but no consensus.

```
> cs_by_chrom <- lapply(cm_by_chrom,
+   function(cm) {
+     ## need to "fix" 'cm' because consensusString()
+     ## doesn't like consensus matrices with columns
+     ## that contain only zeroes (e.g., chromosome
+     ## positions with no coverage)
+     idx <- colSums(cm) == 0L
+     cm["+", idx] <- 1
+     DNASTring(consensusString(cm, ambiguityMap="N"))
+   })
```

The new consensus strings.

```
> cs_by_chrom
```

```
$seq1
1575-letter "DNASTring" instance
seq: NANTAGNNNCTCANTTTAAANNTTTNTTTT...AATNATANNTTTNTNTTTNTCTGNAC+++++
```

```
$seq2
 1584-letter "DNAString" instance
seq: ++++++...NNNANANANACTNNA+++++
```

2.16 How to compute binned averages along a genome

In some applications, there is the need to compute the average of a variable along a genome for a set of predefined fixed-width regions (sometimes called "bins"). One such example is coverage. Coverage is an `RleList` with one list element per chromosome. Here we simulate a coverage list.

```
> library(BSgenome.Scerevisiae.UCSC.sacCer2)
> set.seed(22)
> cov <- RleList(
+   lapply(seqlengths(Scerevisiae),
+     function(len) Rle(sample(-10:10, len, replace=TRUE))),
+   compress=FALSE)
> head(cov, 3)

RleList of length 3
$chrI
integer-Rle of length 230208 with 219146 runs
  Lengths:  1  1  1  1  1  1  1 ...  1  1  1  1  1  1  1
  Values : -4 -1 10  0  7  5  2 ...  4 -2 -8  1 -10 -8 -10

$chrII
integer-Rle of length 813178 with 774522 runs
  Lengths:  1  1  1  1  1  1  1 ...  1  1  1  2  2  1  1
  Values : -3 -6 -7 -3  9 -4 -10 ... -3 -4 -5  2 -2 -8  0

$chrIII
integer-Rle of length 316617 with 301744 runs
  Lengths:  1  1  1  1  1  1  1 ...  1  1  1  1  1  1  1
  Values :  2 -3 -6  5  9  5  3 ...  4 -7 -10 -5 -10 -1 -3
```

Use the `tileGenome` function to create a set of bins along the genome.

```
> bins1 <- tileGenome(seqinfo(Scerevisiae), tilewidth=100,
+   cut.last.tile.in.chrom=TRUE)
```

We define the following function to compute the binned average of a numerical variable defined along a genome.

Arguments:

- 'bins': a `GRanges` object representing the genomic bins.
Typically obtained by calling `tileGenome()` with
'cut.last.tile.in.chrom=TRUE'.
- 'numvar': a named `RleList` object representing a numerical
variable defined along the genome covered by 'bins', which
is the genome described by 'seqinfo(bins)'.
- 'mcolname': the name to give to the metadata column that will
contain the binned average in the returned object.

The function returns 'bins' with an additional metadata column named 'mcolname' containing the binned average.

```
> binnedAverage <- function(bins, numvar, mcolname)
+ {
+   stopifnot(is(bins, "GRanges"))
```

```
+ stopifnot(is(numvar, "RleList"))
+ stopifnot(identical(seqlevels(bins), names(numvar)))
+ bins_per_chrom <- split(ranges(bins), seqnames(bins))
+ means_list <- lapply(names(numvar),
+   function(seqname) {
+     views <- Views(numvar[[seqname]],
+       bins_per_chrom[[seqname]])
+     viewMeans(views)
+   })
+ new_mcol <- unsplit(means_list, as.factor(seqnames(bins)))
+ mcols(bins)[[mcolname]] <- new_mcol
+ bins
+ }
```

Compute the binned average for 'cov':

```
> bins1 <- binnedAverage(bins1, cov, "binned_cov")
> bins1
```

GRanges with 121639 ranges and 1 metadata column:

	seqnames	ranges	strand		binned_cov

seqlengths:

chrI	chrII	chrIII	chrIV	...	chrXV	chrXVI	chrM	2micron
230208	813178	316617	1531919	...	1091289	948062	85779	6318

The bin size can be modified with the `tilewidth` argument to `tileGenome`. For additional examples see `?tileGenome`.

3 Session Information

R version 3.1.1 (2014-07-10)

Platform: i386-w64-mingw32/i386 (32-bit)
