

# Package ‘mia’

October 18, 2022

**Type** Package

**Version** 1.4.0

**Title** Microbiome analysis

**Description** mia implements tools for microbiome analysis based on the SummarizedExperiment, SingleCellExperiment and TreeSummarizedExperiment infrastructure. Data wrangling and analysis in the context of taxonomic data is the main scope. Additional functions for common task are implemented such as community indices calculation and summarization.

**biocViews** Microbiome, Software, DataImport

**License** Artistic-2.0 | file LICENSE

**Encoding** UTF-8

**LazyData** false

**Depends** R (>= 4.0), SummarizedExperiment, SingleCellExperiment, TreeSummarizedExperiment (>= 1.99.3), MultiAssayExperiment

**Imports** methods, stats, utils, MASS, ape, decontam, vegan, BiocGenerics, S4Vectors, IRanges, Biostrings, DECIPHER, BiocParallel, DelayedArray, DelayedMatrixStats, scuttle, scatter, DirichletMultinomial, rlang, dplyr, tibble, tidyr

**Suggests** testthat, knitr, patchwork, BiocStyle, yaml, phyloseq, dada2, stringr, biomformat, reldist, ade4, microbiomeDataSets, rmarkdown

**URL** <https://github.com/microbiome/mia>

**BugReports** <https://github.com/microbiome/mia/issues>

**Roxygen** list(markdown = TRUE)

**RoxygenNote** 7.1.2

**VignetteBuilder** knitr

**git\_url** <https://git.bioconductor.org/packages/mia>

**git\_branch** RELEASE\_3\_15

**git\_last\_commit** 18fd690

**git\_last\_commit\_date** 2022-04-26

**Date/Publication** 2022-10-18

**Author** Felix G.M. Ernst [aut, cre] (<<https://orcid.org/0000-0001-5064-0928>>),

mia-package	<i>mia Package.</i>
-------------	---------------------

---

## Description

`mia` implements tools for microbiome analysis based on the `SummarizedExperiment`, `SingleCellExperiment` and `TreeSummarizedExperiment` infrastructure. Data wrangling and analysis in the context of taxonomic data is the main scope. Additional functions for common task are implemented such as community indices calculation and summarization.

## See Also

[TreeSummarizedExperiment](#) class

---

agglomerate-methods	<i>Agglomerate data using taxonomic information</i>
---------------------	---

---

## Description

`agglomerateByRank` can be used to sum up data based on the association to certain taxonomic ranks given as `rowData`. Only available `taxonomyRanks` can be used.

## Usage

```
## S4 method for signature 'SummarizedExperiment'
agglomerateByRank(
  x,
  rank = taxonomyRanks(x)[1],
  onRankOnly = FALSE,
  na.rm = FALSE,
  empty.fields = c(NA, "", " ", "\t", "-", "_"),
  ...
)

## S4 method for signature 'SingleCellExperiment'
agglomerateByRank(x, ..., altexp = NULL, strip_altexp = TRUE)

## S4 method for signature 'TreeSummarizedExperiment'
agglomerateByRank(x, ..., agglomerateTree = FALSE)
```

**Arguments**

<code>x</code>	a <a href="#">SummarizedExperiment</a> object
<code>rank</code>	a single character defining a taxonomic rank. Must be a value of <code>taxonomyRanks()</code> function.
<code>onRankOnly</code>	TRUE or FALSE: Should information only from the specified rank be used or from ranks equal and above? See details. (default: <code>onRankOnly = FALSE</code> )
<code>na.rm</code>	TRUE or FALSE: Should taxa with an empty rank be removed? Use it with caution, since empty entries on the selected rank will be dropped. This setting can be tweaked by defining <code>empty.fields</code> to your needs. (default: <code>na.rm = TRUE</code> )
<code>empty.fields</code>	a character value defining, which values should be regarded as empty. (Default: <code>c(NA, "", " ", "\t")</code> ). They will be removed if <code>na.rm = TRUE</code> before agglomeration.
<code>...</code>	arguments passed to <code>agglomerateByRank</code> function for <code>SummarizedExperiment</code> objects, <a href="#">mergeRows</a> and <a href="#">sumCountsAcrossFeatures</a> . <ul style="list-style-type: none"> <li><code>remove_empty_ranks</code> A single boolean value for selecting whether to remove those columns of <code>rowData</code> that include only NAs after agglomeration. (By default: <code>remove_empty_ranks = FALSE</code>)</li> </ul>
<code>altexp</code>	String or integer scalar specifying an alternative experiment containing the input data.
<code>strip_altexp</code>	TRUE or FALSE: Should alternative experiments be removed prior to agglomeration? This prevents to many nested alternative experiments by default (default: <code>strip_altexp = TRUE</code> )
<code>agglomerateTree</code>	TRUE or FALSE: should <code>rowTree()</code> also be agglomerated? (Default: <code>agglomerateTree = FALSE</code> )

**Details**

Based on the available taxonomic data and its structure setting `onRankOnly = TRUE` has certain implications on the interpretability of your results. If no loops exist (loops meaning two higher ranks containing the same lower rank), the results should be comparable. you can check for loops using [detectLoop](#).

Agglomeration sum up values of assays at specified taxonomic level. Certain assays, e.g. those that include binary or negative values, can lead to meaningless values, when values are summed. In those cases, consider doing agglomeration first and then transformation.

**Value**

A taxonomically-agglomerated, optionally-pruned object of the same class as `x`.

**See Also**

[mergeRows](#), [sumCountsAcrossFeatures](#)

**Examples**

```

data(GlobalPatterns)
# print the available taxonomic ranks
colnames(rowData(GlobalPatterns))
taxonomyRanks(GlobalPatterns)

# agglomerate at the Family taxonomic rank
x1 <- agglomerateByRank(GlobalPatterns, rank="Family")
## How many taxa before/after agglomeration?
nrow(GlobalPatterns)
nrow(x1)

# with agglomeration of the tree
x2 <- agglomerateByRank(GlobalPatterns, rank="Family",
                        agglomerateTree = TRUE)
nrow(x2) # same number of rows, but
rowTree(x1) # ... different
rowTree(x2) # ... tree

# If assay contains binary or negative values, summing might lead to meaningless
# values, and you will get a warning. In these cases, you might want to do
# agglomeration again at chosen taxonomic level.
tse <- transformSamples(GlobalPatterns, method = "pa")
tse <- agglomerateByRank(tse, rank = "Genus")
tse <- transformSamples(tse, method = "pa")

# removing empty labels by setting na.rm = TRUE
sum(is.na(rowData(GlobalPatterns)$Family))
x3 <- agglomerateByRank(GlobalPatterns, rank="Family", na.rm = TRUE)
nrow(x3) # different from x2

# Because all the rownames are from the same rank, rownames do not include
# prefixes, in this case "Family:".
print(rownames(x3[1:3,]))

# To add them, use getTaxonomyLabels function.
rownames(x3) <- getTaxonomyLabels(x3, with_rank = TRUE)
print(rownames(x3[1:3,]))

# use 'remove_empty_ranks' to remove columns that include only NAs
x4 <- agglomerateByRank(GlobalPatterns, rank="Phylum", remove_empty_ranks = TRUE)
head(rowData(x4))

## Look at enterotype dataset...
data(enterotype)
## print the available taxonomic ranks. Shows only 1 rank available
## not useful for agglomerateByRank
taxonomyRanks(enterotype)

```

```
calculateDistance(tse)

## End(Not run)
```

---

calculatedDMN	<i>Dirichlet-Multinomial Mixture Model: Machine Learning for Microbiome Data</i>
---------------	--

---

## Description

These functions are accessors for functions implemented in the [DirichletMultinomial](#) package

## Usage

```
calculateDMN(x, ...)

## S4 method for signature 'ANY'
calculateDMN(
  x,
  k = 1,
  BPPARAM = SerialParam(),
  seed = runif(1, 0, .Machine$integer.max),
  ...
)

## S4 method for signature 'SummarizedExperiment'
calculateDMN(
  x,
  abund_values = exprs_values,
  exprs_values = "counts",
  transposed = FALSE,
  ...
)

runDMN(x, name = "DMN", ...)

getDMN(x, name = "DMN", ...)

## S4 method for signature 'SummarizedExperiment'
getDMN(x, name = "DMN")

bestDMNFit(x, name = "DMN", type = c("laplace", "AIC", "BIC"), ...)

## S4 method for signature 'SummarizedExperiment'
bestDMNFit(x, name = "DMN", type = c("laplace", "AIC", "BIC"))
```

```
getBestDMNFit(x, name = "DMN", type = c("laplace", "AIC", "BIC"), ...)  
  
## S4 method for signature 'SummarizedExperiment'  
getBestDMNFit(x, name = "DMN", type = c("laplace", "AIC", "BIC"))  
  
calculateDMNgroup(x, ...)  
  
## S4 method for signature 'ANY'  
calculateDMNgroup(  
  x,  
  variable,  
  k = 1,  
  seed = runif(1, 0, .Machine$integer.max),  
  ...  
)  
  
## S4 method for signature 'SummarizedExperiment'  
calculateDMNgroup(  
  x,  
  variable,  
  abund_values = exprs_values,  
  exprs_values = "counts",  
  transposed = FALSE,  
  ...  
)  
  
performDMNgroupCV(x, ...)  
  
## S4 method for signature 'ANY'  
performDMNgroupCV(  
  x,  
  variable,  
  k = 1,  
  seed = runif(1, 0, .Machine$integer.max),  
  ...  
)  
  
## S4 method for signature 'SummarizedExperiment'  
performDMNgroupCV(  
  x,  
  variable,  
  abund_values = exprs_values,  
  exprs_values = "counts",  
  transposed = FALSE,  
  ...  
)
```

**Arguments**

x	a numeric matrix with samples as rows or a <a href="#">SummarizedExperiment</a> object.
...	optional arguments not used.
k	the number of Dirichlet components to fit. See <a href="#">dmn</a>
BPPARAM	A <a href="#">BiocParallelParam</a> object specifying whether the UniFrac calculation should be parallelized.
seed	random number seed. See <a href="#">dmn</a>
abund_values	a single character value for specifying which assay to use for calculation.
exprs_values	a single character value for specifying which assay to use for calculation. (Please use abund_values instead. At some point exprs_values will be disabled.)
transposed	Logical scalar, is x transposed with samples in rows?
name	the name to store the result in <a href="#">metadata</a>
type	the type of measure used for the goodness of fit. One of 'laplace', 'AIC' or 'BIC'.
variable	a variable from colData to use as a grouping variable. Must be a character of factor.

**Value**

calculateDMN and getDMN return a list of DMN objects, one element for each value of k provided.  
 bestDMNFit returns the index for the best fit and getBestDMNFit returns a single DMN object.  
 calculateDMNgroup returns a [DMNGroup](#) object  
 performDMNgroupCV returns a data.frame

**See Also**

[DMN-class](#), [DMNGroup-class](#), [dmn](#), [dmngroup](#), [cvdmn](#), [accessors for DMN objects](#)

**Examples**

```
f1 <- system.file(package="DirichletMultinomial", "extdata", "Twins.csv")
counts <- as.matrix(read.csv(f1, row.names=1))
f1 <- system.file(package="DirichletMultinomial", "extdata", "TwinStudy.t")
pheno0 <- scan(f1)
lvls <- c("Lean", "Obese", "Overwt")
pheno <- factor(lvls[pheno0 + 1], levels=lvls)
colData <- DataFrame(pheno = pheno)

tse <- TreeSummarizedExperiment(assays = list(counts = counts),
                               colData = colData)

#
dmn <- calculateDMN(tse)
dmn[[1L]]
```

```

# since this take a bit of resources to calculate for k > 1, the data is
# loaded
## Not run:
tse <- runDMN(tse, name = "DMN", k = 1:7)

## End(Not run)
data(dmn_se)
# Convert SE to TreeSE to enable all features of mia and TreeSE object
# (Optional step at this point)
dmn_tse <- as(dmn_se, "TreeSummarizedExperiment")
names(metadata(dmn_tse))

# return a list of DMN objects
getDMN(dmn_tse)
# return, which objects fits best
bestDMNFit(dmn_tse, type = "laplace")
# return the model, which fits best
getBestDMNFit(dmn_tse, type = "laplace")

```

---

calculateJSD

*Calculate the Jensen-Shannon Divergence*

---

### Description

This function calculates the Jensen-Shannon Divergence (JSD) in a [SummarizedExperiment](#) object.

### Usage

```

## S4 method for signature 'ANY'
calculateJSD(x, ...)

## S4 method for signature 'SummarizedExperiment'
calculateJSD(
  x,
  abund_values = exprs_values,
  exprs_values = "counts",
  transposed = FALSE,
  ...
)

runJSD(x, BPPARAM = SerialParam(), chunkSize = nrow(x))

```

### Arguments

x                    a numeric matrix or a [SummarizedExperiment](#).

...                   optional arguments not used.

abund\_values        a single character value for specifying which assay to use for calculation.

exprs_values	a single character value for specifying which assay to use for calculation. (Please use abund_values instead. At some point exprs_values will be disabled.)
transposed	Logical scalar, is x transposed with cells in rows?
BPPARAM	A <code>BiocParallelParam</code> object specifying whether the JSD calculation should be parallelized.
chunkSize	an integer scalar, defining the size of data send to the individual worker. Only has an effect, if BPPARAM defines more than one worker. (default: chunkSize = nrow(x))

**Value**

a sample-by-sample distance matrix, suitable for NMDS, etc.

**Author(s)**

Susan Holmes <susan@stat.stanford.edu>. Adapted for phyloseq by Paul J. McMurdie. Adapted for mia by Felix G.M. Ernst

**References**

Jensen-Shannon Divergence and Hilbert space embedding. Bent Fuglede and Flemming Topsøe University of Copenhagen, Department of Mathematics <http://www.math.ku.dk/~topsoe/ISIT2004JSD.pdf>

**See Also**

[http://en.wikipedia.org/wiki/Jensen-Shannon\\_divergence](http://en.wikipedia.org/wiki/Jensen-Shannon_divergence)

**Examples**

```
data(enterotype)
library(scater)

jsd <- calculateJSD(enterotype)
class(jsd)
head(jsd)

enterotype <- runMDS(enterotype, FUN = calculateJSD, name = "JSD",
                    exprs_values = "counts")
head(reducedDim(enterotype))
head(attr(reducedDim(enterotype), "eig"))
attr(reducedDim(enterotype), "GOF")
```

---

calculateOverlap      *Estimate overlap*

---

### Description

This function calculates overlap for all sample-pairs in a [SummarizedExperiment](#) object.

### Usage

```
calculateOverlap(x, abund_values = "counts", detection = 0, ...)  
  
## S4 method for signature 'SummarizedExperiment'  
calculateOverlap(x, abund_values = "counts", detection = 0, ...)  
  
runOverlap(x, ...)  
  
## S4 method for signature 'SummarizedExperiment'  
runOverlap(x, name = "overlap", ...)
```

### Arguments

x	a <a href="#">SummarizedExperiment</a> object containing a tree.
abund_values	A single character value for selecting the <a href="#">assay</a> to calculate the overlap.
detection	A single numeric value for selecting detection threshold for absence/presence of features. Feature that has abundance under threshold in either of samples, will be discarded when evaluating overlap between samples.
...	Optional arguments not used.
name	A single character value specifying the name of overlap matrix that is stored in <code>reducedDim(x)</code> .

### Details

These function calculates overlap between all the sample-pairs. Overlap reflects similarity between sample-pairs.

When overlap is calculated using relative abundances, the higher the value the higher the similarity is. When using relative abundances, overlap value 1 means that all the abundances of features are equal between two samples, and 0 means that samples have completely different relative abundances.

### Value

calculateOverlap returns sample-by-sample distance matrix. runOverlap returns x that includes overlap matrix in its reducedDim.

### Author(s)

Leo Lahti and Tuomas Borman. Contact: [microbiome.github.io](https://microbiome.github.io)

**See Also**

[calculateJSD](#) [calculateUniFrac](#)

**Examples**

```
data(esophagus)
tse <- esophagus
tse <- transformSamples(tse, method = "relabundance")
overlap <- calculateOverlap(tse, abund_values = "relabundance")
overlap

# Store result to reducedDim
tse <- runOverlap(tse, abund_values = "relabundance", name = "overlap_between_samples")
head(reducedDims(tse)$overlap_between_samples)
```

---

calculateUnifrac	<i>Calculate weighted or unweighted (Fast) Unifrac distance</i>
------------------	---

---

**Description**

This function calculates the (Fast) Unifrac distance for all sample-pairs in a [TreeSummarizedExperiment](#) object.

**Usage**

```
calculateUnifrac(x, tree, ...)

## S4 method for signature 'ANY,phylo'
calculateUnifrac(
  x,
  tree,
  weighted = FALSE,
  normalized = TRUE,
  BPPARAM = SerialParam()
)

## S4 method for signature 'TreeSummarizedExperiment,missing'
calculateUnifrac(
  x,
  abund_values = exprs_values,
  exprs_values = "counts",
  transposed = FALSE,
  ...
)

calculateUniFrac(x, ...)
```

```
## S4 method for signature 'ANY'
calculateUniFrac(x, ...)

runUniFrac(
  x,
  tree,
  weighted = FALSE,
  normalized = TRUE,
  BPPARAM = SerialParam()
)
```

### Arguments

x	a numeric matrix or a <a href="#">TreeSummarizedExperiment</a> object containing a tree. Please note that <code>runUniFrac</code> expects a matrix with samples per row and not per column. This is implemented to be compatible with other distance calculations such as <code>dist</code> as much as possible.
tree	if x is a matrix, a <a href="#">phylo</a> object matching the matrix. This means that the phylo object and the columns should relate to the same type of features (aka. microorganisms).
...	optional arguments not used.
weighted	TRUE or FALSE: Should use weighted-Unifrac calculation? Weighted-Unifrac takes into account the relative abundance of species/taxa shared between samples, whereas unweighted-Unifrac only considers presence/absence. Default is FALSE, meaning the unweighted-Unifrac distance is calculated for all pairs of samples.
normalized	TRUE or FALSE: Should the output be normalized such that values range from 0 to 1 independent of branch length values? Default is TRUE. Note that (unweighted) Unifrac is always normalized by total branch-length, and so this value is ignored when <code>weighted == FALSE</code> .
BPPARAM	A <a href="#">BiocParallelParam</a> object specifying whether the Unifrac calculation should be parallelized.
abund_values	a single character value for specifying which assay to use for calculation.
exprs_values	a single character value for specifying which assay to use for calculation. (Please use <code>abund_values</code> instead. At some point <code>exprs_values</code> will be disabled.)
transposed	Logical scalar, is x transposed with cells in rows, i.e., is Unifrac distance calculated based on rows (FALSE) or columns (TRUE). (By default: <code>transposed = FALSE</code> )

### Details

Please note that if `calculateUniFrac` is used as a FUN for `runMDS`, the argument `ntop` has to be set to `nrow(x)`.

**Value**

a sample-by-sample distance matrix, suitable for NMDS, etc.

**Author(s)**

Paul J. McMurdie. Adapted for mia by Felix G.M. Ernst

**References**

The main implementation (Fast Unifrac) is adapted from the algorithm's description in:

Hamady, Lozupone, and Knight, "Fast UniFrac: facilitating high-throughput phylogenetic analyses of microbial communities including analysis of pyrosequencing and PhyloChip data." *The ISME Journal* (2010) 4, 17–27.

See also additional descriptions of Unifrac in the following articles:

Lozupone, Hamady and Knight, "Unifrac - An Online Tool for Comparing Microbial Community Diversity in a Phylogenetic Context.", *BMC Bioinformatics* 2006, 7:371

Lozupone, Hamady, Kelley and Knight, "Quantitative and qualitative (beta) diversity measures lead to different insights into factors that structure microbial communities." *Appl Environ Microbiol.* 2007

Lozupone C, Knight R. "Unifrac: a new phylogenetic method for comparing microbial communities." *Appl Environ Microbiol.* 2005 71 (12):8228-35.

**Examples**

```
data(esophagus)
library(scater)
calculateUnifrac(esophagus, weighted = FALSE)
calculateUnifrac(esophagus, weighted = TRUE)
calculateUnifrac(esophagus, weighted = TRUE, normalized = FALSE)
# for using calculateUnifrac in conjunction with runMDS the tree argument
# has to be given separately. In addition, subsetting using ntop must
# be disabled
esophagus <- runMDS(esophagus, FUN = calculateUnifrac, name = "Unifrac",
                    tree = rowTree(esophagus),
                    exprs_values = "counts",
                    ntop = nrow(esophagus))
reducedDim(esophagus)
```

---

estimateDivergence

*Estimate divergence*

---

**Description**

This function estimates a divergence within samples.

**Usage**

```

estimateDivergence(
  x,
  abund_values = "counts",
  name = "divergence",
  reference = "median",
  FUN = vegan::vegdist,
  method = "bray",
  ...
)

## S4 method for signature 'SummarizedExperiment'
estimateDivergence(
  x,
  abund_values = "counts",
  name = "divergence",
  reference = "median",
  FUN = vegan::vegdist,
  method = "bray",
  ...
)

```

**Arguments**

x	a <a href="#">SummarizedExperiment</a> object
abund_values	the name of the assay used for calculation of the sample-wise estimates
name	a name for the column of the colData the results should be stored in. By default, name is "divergence".
reference	a numeric vector that has length equal to number of features, or a non-empty character value; either 'median' or 'mean'. reference specifies the reference that is used to calculate divergence. by default, reference is "median".
FUN	a function for distance calculation. The function must expect the input matrix as its first argument. With rows as samples and columns as features. By default, FUN is <code>vegan::vegdist</code> .
method	a method that is used to calculate the distance. Method is passed to the function that is specified by FUN. By default, method is "bray".
...	optional arguments

**Details**

Microbiota divergence (heterogeneity / spread) within a given sample set can be quantified by the average sample dissimilarity or beta diversity with respect to a given reference sample.

This measure is sensitive to sample size. Subsampling or bootstrapping can be applied to equalize sample sizes between comparisons.

**Value**

x with additional `colData` named `*name*`

**Author(s)**

  x,
  tree = "missing",
  abund_values = "counts",
  name = "faith",
  ...
)
```

### Arguments

x	a <a href="#">SummarizedExperiment</a> object
abund_values	the name of the assay used for calculation of the sample-wise estimates.
index	a character vector, specifying the diversity measures to be calculated.
name	a name for the column(s) of the colData the results should be stored in.
...	optional arguments: <ul style="list-style-type: none"> <li>• <code>threshold</code> A numeric value in the unit interval, determining the threshold for coverage index. By default, <code>threshold</code> is 0.9.</li> <li>• <code>quantile</code> Arithmetic abundance classes are evenly cut up to to this quantile of the data. The assumption is that abundances higher than this are not common, and they are classified in their own group. By default, <code>quantile</code> is 0.5.</li> <li>• <code>num_of_classes</code> The number of arithmetic abundance classes from zero to the quantile cutoff indicated by <code>quantile</code>. By default, <code>num_of_classes</code> is 50.</li> </ul>
BPPARAM	A <a href="#">BiocParallelParam</a> object specifying whether calculation of estimates should be parallelized.
tree	A phylogenetic tree that is used to calculate 'faith' index. If x is a <a href="#">TreeSummarizedExperiment</a> , <code>rowTree(x)</code> is used by default.

### Details

The available indices include the 'Coverage', 'Faith's phylogenetic diversity', 'Fisher alpha', 'Gini-Simpson', 'Inverse Simpson', 'log-modulo skewness', and 'Shannon' diversity indices. See details for more information and references.

Diversity is a joint quantity that combines elements or community richness and evenness. Diversity increases, in general, when species richness or evenness increase.

By default, this function returns all indices.

- 'coverage' Number of species needed to cover a given fraction of the ecosystem (50 percent by default). Tune this with the `threshold` argument.
- 'faith' Faith's phylogenetic alpha diversity index measures how long the taxonomic distance is between taxa that are present in the sample. Larger values represent higher diversity. (Faith 1992)
- 'fisher' Fisher's alpha; as implemented in [vegan::fisher.alpha](#). (Fisher et al. 1943)

- 'gini\_simpson' Gini-Simpson diversity i.e.  $1 - \lambda$ , where  $\lambda$  is the Simpson index, calculated as the sum of squared relative abundances. This corresponds to the diversity index 'simpson' in `vegan::diversity`. This is also called Gibbs–Martin, or Blau index in sociology, psychology and management studies. The Gini-Simpson index ( $1 - \lambda$ ) should not be confused with Simpson's dominance ( $\lambda$ ), Gini index, or inverse Simpson index ( $1/\lambda$ ).
- 'inverse\_simpson' Inverse Simpson diversity:  $1/\lambda$  where  $\lambda = \sum(p^2)$  and  $p$  refers to relative abundances. This corresponds to the diversity index 'invsimpson' in `vegan::diversity`. Don't confuse this with the closely related Gini-Simpson index
- 'log\_modulo\_skewness' The rarity index characterizes the concentration of species at low abundance. Here, we use the skewness of the frequency distribution of arithmetic abundance classes (see Magurran & McGill 2011). These are typically right-skewed; to avoid taking log of occasional negative skews, we follow Locey & Lennon (2016) and use the log-modulo transformation that adds a value of one to each measure of skewness to allow logarithmization.
- 'shannon' Shannon diversity (entropy).

estimateDominance	<i>Estimate dominance measures</i>
-------------------	------------------------------------

---

## Description

This function calculates community dominance indices. This includes the ‘Absolute’, ‘Berger-Parker’, ‘Core abundance’, ‘Gini’, ‘McNaughton’s’, ‘Relative’, and ‘Simpson’s’ indices.

## Usage

```

estimateDominance(
  x,
  abund_values = "counts",
  index = c("absolute", "dbp", "core_abundance", "gini", "dmn", "relative",
           "simpson_lambda"),
  ntaxa = 1,
  aggregate = TRUE,
  name = index,
  ...,
  BPPARAM = SerialParam()
)

## S4 method for signature 'SummarizedExperiment'
estimateDominance(
  x,
  abund_values = "counts",
  index = c("absolute", "dbp", "core_abundance", "gini", "dmn", "relative",
           "simpson_lambda"),
  ntaxa = 1,
  aggregate = TRUE,
  name = index,
  ...,
  BPPARAM = SerialParam()
)

```

**Arguments**

x	a <a href="#">SummarizedExperiment</a> object
abund_values	A single character value for selecting the <a href="#">assay</a> to calculate the sample-wise estimates.
index	a character vector, specifying the indices to be calculated.
ntaxa	Optional and only used for the Absolute and Relative dominance indices: The n-th position of the dominant taxa to consider (default: ntaxa = 1). Disregarded for the indices “dbp”, “core_abundance”, “Gini”, “dmn”, and “Simpson”.
aggregate	Optional and only used for the Absolute, dbp, Relative, and dmn dominance indices: Aggregate the values for top members selected by ntaxa or not. If TRUE, then the sum of relative abundances is returned. Otherwise the relative abundance is returned for the single taxa with the indicated rank (default: aggregate = TRUE). Disregarded for the indices “core_abundance”, “gini”, “dmn”, and “simpson”.
name	A name for the column(s) of the colData where the calculated Dominance indices should be stored in.
...	additional arguments currently not used.
BPPARAM	A <a href="#">BiocParallelParam</a> object specifying whether calculation of estimates should be parallelized. (Currently not used)

**Details**

A dominance index quantifies the dominance of one or few species in a community. Greater values indicate higher dominance.

Dominance indices are in general negatively correlated with alpha diversity indices (species richness, evenness, diversity, rarity). More dominant communities are less diverse.

estimateDominance calculates the following community dominance indices:

- ‘absolute’ Absolute index equals to the absolute abundance of the most dominant n species of the sample (specify the number with the argument ntaxa). Index gives positive integer values.
- ‘dbp’ Berger-Parker index (See Berger & Parker 1970) calculation is a special case of the ‘relative’ index. dbp is the relative abundance of the most abundant species of the sample. Index gives values in interval 0 to 1, where bigger value represent greater dominance.

$$dbp = \frac{N_1}{N_{tot}}$$

where  $N_1$  is the absolute abundance of the most dominant species and  $N_{tot}$  is the sum of absolute abundances of all species.

- ‘core\_abundance’ Core abundance index is related to core species. Core species are species that are most abundant in all samples, i.e., in whole data set. Core species are defined as those species that have prevalence over 50\ species must be prevalent in 50\ calculate the core abundance index. Core abundance index is sum of relative abundances of core species in the sample. Index gives values in interval 0 to 1, where bigger value represent greater dominance.

$$core\_abundance = \frac{N_{core}}{N_{tot}}$$

where  $N_{core}$  is the sum of absolute abundance of the core species and  $N_{tot}$  is the sum of absolute abundances of all species.

- 'gini' Gini index is probably best-known from socio-economic contexts (Gini 1921). In economics, it is used to measure, for example, how unevenly income is distributed among population. Here, Gini index is used similarly, but income is replaced with abundance.

If there is small group of species that represent large portion of total abundance of microbes, the inequality is large and Gini index closer to 1. If all species has equally large abundances, the equality is perfect and Gini index equals 0. This index should not be confused with Gini-Simpson index, which quantifies diversity.

- 'dmn' McNaughton's index is the sum of relative abundances of the two most abundant species of the sample (McNaughton & Wolf, 1970). Index gives values in the unit interval:

$$dmn = (N_1 + N_2)/N_{tot}$$

where  $N_1$  and  $N_2$  are the absolute abundances of the two most dominant species and  $N_{tot}$  is the sum of absolute abundances of all species.

- 'relative' Relative index equals to the relative abundance of the most dominant n species of the sample (specify the number with the argument `ntaxa`). This index gives values in interval 0 to 1.

$$relative = N_1/N_{tot}$$

where  $N_1$  is the absolute abundance of the most dominant species and  $N_{tot}$  is the sum of absolute abundances of all species.

- 'simpson\_lambda' Simpson's (dominance) index or Simpson's lambda is the sum of squared relative abundances. This index gives values in the unit interval. This value equals the probability that two randomly chosen individuals belongs to the same species. The higher the probability, the greater the dominance (See e.g. Simpson 1949).

$$lambda = \sum(p^2)$$

where p refers to relative abundances.

There is also a more advanced Simpson dominance index (Simpson 1949). However, this is not provided and the simpler squared sum of relative abundances is used instead as the alternative index is not in the unit interval and it is highly correlated with the simpler variant implemented here.

estimateEvenness	<i>Estimate Evenness measures</i>
------------------	-----------------------------------

---

## Description

This function calculates community evenness indices. These include the ‘Camargo’, ‘Pielou’, ‘Simpson’, ‘Evar’ and ‘Bulla’ evenness measures. See details for more information and references.

## Usage

```

estimateEvenness(
  x,
  abund_values = "counts",
  index = c("pielou", "camargo", "simpson_evenness", "evar", "bulla"),
  name = index,
  ...
)

## S4 method for signature 'SummarizedExperiment'
estimateEvenness(
  x,
  abund_values = "counts",
  index = c("camargo", "pielou", "simpson_evenness", "evar", "bulla"),
  name = index,
  ...,
  BPPARAM = SerialParam()
)

```

## Arguments

x	a <a href="#">SummarizedExperiment</a> object
abund_values	A single character value for selecting the <a href="#">assay</a> used for calculation of the sample-wise estimates.
index	a character vector, specifying the evenness measures to be calculated.
name	a name for the column(s) of the colData the results should be stored in.
...	optional arguments: <ul style="list-style-type: none"> <li>• threshold a numeric threshold. assay values below or equal to this threshold will be set to zero.</li> </ul>

BPPARAM A `BiocParallelParam` object specifying whether calculation of estimates should be parallelized.

## Details

Evenness is a standard index in community ecology, and it quantifies how evenly the abundances of different species are distributed. The following evenness indices are provided:

By default, this function returns all indices.

The available evenness indices include the following (all in lowercase):

- 'camargo' Camargo's evenness (Camargo 1992)
- 'simpson\_evenness' Simpson's evenness is calculated as inverse Simpson diversity ( $1/\lambda$ ) divided by observed species richness  $S$ :  $(1/\lambda)/S$ .
- 'pielou' Pielou's evenness (Pielou, 1966), also known as Shannon or Shannon-Weaver/Wiener/Weiner evenness;  $H/\ln(S)$ . The Shannon-Weaver is the preferred term; see Spellerberg and Fedor (2003).
- 'evar' Smith and Wilson's Evar index (Smith & Wilson 1996).
- 'bulla' Bulla's index (O) (Bulla 1994).

Desirable statistical evenness metrics avoid strong bias towards very large or very small abundances; are independent of richness; and range within the unit interval with increasing evenness (Smith & Wilson 1996). Evenness metrics that fulfill these criteria include at least camargo, simpson, smith-wilson, and bulla. Also see Magurran & McGill (2011) and Beisel et al. (2003) for further details.

  x,
  abund_values = "counts",
  index = c("ace", "chao1", "hill", "observed"),
```

```

    name = index,
    detection = 0,
    ...,
    BPPARAM = SerialParam()
  )

```

## Arguments

x	a <a href="#">SummarizedExperiment</a> object
abund_values	the name of the assay used for calculation of the sample-wise estimates
index	a character vector, specifying the richness measures to be calculated.
name	a name for the column(s) of the colData the results should be stored in.
detection	a numeric value for selecting detection threshold for the abundances. The default detection threshold is 0.
...	additional parameters passed to estimateRichness
BPPARAM	A <a href="#">BiocParallelParam</a> object specifying whether calculation of estimates should be parallelized.

## Details

These include the ‘ace’, ‘Chao1’, ‘Hill’, and ‘Observed’ richness measures. See details for more information and references.

The richness is calculated per sample. This is a standard index in community ecology, and it provides an estimate of the number of unique species in the community. This is often not directly observed for the whole community but only for a limited sample from the community. This has led to alternative richness indices that provide different ways to estimate the species richness.

Richness index differs from the concept of species diversity or evenness in that it ignores species abundance, and focuses on the binary presence/absence values that indicate simply whether the species was detected.

The function takes all index names in full lowercase. The user can provide the desired spelling through the argument [name](#) (see examples).

The following richness indices are provided.

- ‘ace’ Abundance-based coverage estimator (ACE) is another nonparametric richness index that uses sample coverage, defined based on the sum of the probabilities of the observed species. This method divides the species into abundant (more than 10 reads or observations) and rare groups in a sample and tends to underestimate the real number of species. The ACE index ignores the abundance information for the abundant species, based on the assumption that the abundant species are observed regardless of their exact abundance. We use here the bias-corrected version (O’Hara 2005, Chiu et al. 2014) implemented in [estimateR](#). For an exact formulation, see [estimateR](#). Note that this index comes with an additional column with standard error information.
- ‘chao1’ This is a nonparametric estimator of species richness. It assumes that rare species carry information about the (unknown) number of unobserved species. We use here the bias-corrected version (O’Hara 2005, Chiu et al. 2014) implemented in [estimateR](#). This index implicitly assumes that every taxa has equal probability of being observed. Note that it gives a

lower bound to species richness. The bias-corrected for an exact formulation, see [estimateR](#). This estimator uses only the singleton and doubleton counts, and hence it gives more weight to the low abundance species. Note that this index comes with an additional column with standard error information.

- 'hill' Effective species richness aka Hill index (see e.g. Chao et al. 2016). Currently only the case 1D is implemented. This corresponds to the exponent of Shannon diversity. Intuitively, the effective richness indicates the number of species whose even distribution would lead to the same diversity than the observed community, where the species abundances are unevenly distributed.
- 'observed' The *observed richness* gives the number of species that is detected above a given detection threshold in the observed sample (default 0). This is conceptually the simplest richness index. The corresponding index in the **vegan** package is "richness".

```

**Description**

These are functions for extracting abundances present in `assay(x)`. These functions are convenience wrapper around subsetting columns or rows from `assay(x, name)`.

**Usage**

```
getAbundanceSample(x, sample_id, abund_values = "counts")

## S4 method for signature 'SummarizedExperiment'
getAbundanceSample(x, sample_id = NULL, abund_values = "counts")

getAbundanceFeature(x, feature_id, abund_values)

## S4 method for signature 'SummarizedExperiment'
getAbundanceFeature(x, feature_id = NULL, abund_values = "counts")
```

**Arguments**

<code>x</code>	A <a href="#">SummarizedExperiment</a> object.
<code>sample_id</code>	A “SampleID” from which user wants to extract the abundances of “FeatureID”. This is essentially a column name in <code>assay(x)</code> .
<code>abund_values</code>	a character value to select an <a href="#">assayNames</a>
<code>feature_id</code>	A “FeatureID” for which user wants to extract the abundances from all of “SampleID” in <a href="#">assayNames</a> . This is essentially a rowname in <code>assay(x)</code> .

**Details**

`getAbundanceSample` returns abundance values for all “FeatureIDs” in a user specified “SampleID”.

`getAbundanceFeature` returns abundance values in all “SampleIDs” for user specified “FeatureID”.

**Value**

`getAbundanceSample` and `getAbundanceFeature` return a numeric matrix of the abundance values for all “SampleIDs”/“FeatureIDs”

**Author(s)**

Sudarshan A. Shetty

**Examples**

```
# getAbundanceSample
data(GlobalPatterns)
getAbundanceSample(GlobalPatterns,
                    sample_id = 'CC1',
                    abund_values = 'counts')

# getAbundanceFeature
getAbundanceFeature(GlobalPatterns,
```

```
feature_id = '522457',
abund_values = 'counts')
```

---

```
getExperimentCrossAssociation
```

*Calculate correlations between features of two experiments.*

---

## Description

Calculate correlations between features of two experiments.

## Usage

```
getExperimentCrossAssociation(x, ...)

## S4 method for signature 'MultiAssayExperiment'
getExperimentCrossAssociation(
  x,
  experiment1 = 1,
  experiment2 = 2,
  abund_values1 = "counts",
  abund_values2 = "counts",
  MARGIN = 1,
  method = c("spearman", "categorical", "kendall", "pearson"),
  mode = "table",
  p_adj_method = c("fdr", "BH", "bonferroni", "BY", "hochberg", "holm", "hommel",
    "none"),
  p_adj_threshold = NULL,
  cor_threshold = NULL,
  sort = FALSE,
  filter_self_correlations = FALSE,
  verbose = TRUE,
  test_significance = FALSE,
  show_warnings = TRUE,
  paired = FALSE,
  ...
)

## S4 method for signature 'SummarizedExperiment'
getExperimentCrossAssociation(x, experiment2 = x, ...)

testExperimentCrossAssociation(x, ...)

## S4 method for signature 'ANY'
testExperimentCrossAssociation(x, ...)

testExperimentCrossCorrelation(x, ...)
```

```
## S4 method for signature 'ANY'
testExperimentCrossCorrelation(x, ...)

getExperimentCrossCorrelation(x, ...)

## S4 method for signature 'ANY'
getExperimentCrossCorrelation(x, ...)
```

## Arguments

x	A <a href="#">MultiAssayExperiment</a> or <a href="#">SummarizedExperiment</a> object.
...	Additional arguments: <ul style="list-style-type: none"> <li>• <code>symmetric</code> A single boolean value for specifying if measure is symmetric or not. When <code>symmetric = TRUE</code>, associations are calculated only for unique variable-pairs, and they are assigned to corresponding variable-pair. This decreases the number of calculations in 2-fold meaning faster execution. (By default: <code>symmetric = FALSE</code>)</li> <li>• <code>association_FUN</code> A function that is used to calculate (dis-)similarity between features. Function must take matrix as an input and give numeric values as an output. Adjust method and other parameters correspondingly. Supported functions are, for example, <code>stats::dist</code> and <code>vegan::vegdist</code>.</li> </ul>
experiment1	A single character or numeric value for selecting the experiment 1 from <code>experiments(x)</code> of <code>MultiassayExperiment</code> object. (By default: <code>experiment1 = 1</code> )
experiment2	A single character or numeric value for selecting the experiment 2 from <code>experiments(x)</code> of <code>MultiAssayExperiment</code> object or <code>altExp(x)</code> of <code>SummarizedExperiment</code> object. Alternatively, <code>experiment2</code> can also be SE object when <code>x</code> is SE object. (By default: <code>experiment2 = 2</code> when <code>x</code> is MAE and <code>experiment2 = x</code> when <code>x</code> is SE)
abund_values1	A single character value for selecting the <a href="#">assay</a> of experiment 1 to be transformed. (By default: <code>abund_values1 = "counts"</code> )
abund_values2	A single character value for selecting the <a href="#">assay</a> of experiment 2 to be transformed. (By default: <code>abund_values2 = "counts"</code> )
MARGIN	A single numeric value for selecting if association are calculated row-wise / for features (1) or column-wise / for samples (2). Must be 1 or 2. (By default: <code>MARGIN = 1</code> )
method	A single character value for selecting association method ('kendall', 'pearson', or 'spearman' for continuous/numeric; 'categorical' for discrete) (By default: <code>method = "spearman"</code> )
mode	A single character value for selecting output format Available formats are 'table' and 'matrix'. (By default: <code>mode = "table"</code> )
p_adj_method	A single character value for selecting adjustment method of p-values. Passed to <code>p.adjust</code> function. (By default: <code>p_adj_method = "fdr"</code> )
p_adj_threshold	A single numeric value (from 0 to 1) for selecting adjusted p-value threshold for filtering. (By default: <code>p_adj_threshold = NULL</code> )

cor_threshold	A single numeric absolute value (from 0 to 1) for selecting correlation threshold for filtering. (By default: cor_threshold = NULL)
sort	A single boolean value for selecting whether to sort features or not in result matrices. Used method is hierarchical clustering. (By default: sort = FALSE)
filter_self_correlations	A single boolean value for selecting whether to filter out correlations between identical items. Applies only when correlation between experiment itself is tested, i.e., when assays are identical. (By default: filter_self_correlations = FALSE)
verbose	A single boolean value for selecting whether to get messages about progress of calculation.
test_significance	A single boolean value for selecting whether to test statistical significance of associations.
show_warnings	A single boolean value for selecting whether to show warnings that might occur when correlations and p-values are calculated.
paired	A single boolean value for specifying if samples are paired or not. colnames must match between twp experiments. paired is disabled when MARGIN = 1. (By default: paired = FALSE)

## Details

These functions calculates associations between features of two experiments. `getExperimentCrossAssociation` calculates only associations by default. `testExperimentCrossAssociation` calculates also significance of associations.

## Value

These functions return associations in table or matrix format. In table format, returned value is a data frame that includes features and associations (and p-values) in columns. In matrix format, returned value is a one matrix when only associations are calculated. If also significances are tested, then returned value is a list of matrices.

## Examples

```
mae <- microbiomeDataSets::peerj32()

# Subset so that less observations / quicker to run, just for example
mae[[1]] <- mae[[1]][1:20, 1:10]
mae[[2]] <- mae[[2]][1:20, 1:10]
# Transform data
mae[[1]] <- transformSamples(mae[[1]], method = "rclr")

# Calculate cross-correlations
result <- getExperimentCrossAssociation(mae, method = "pearson")
```

```

# Show first 5 entries
head(result, 5)

# Same can be done with SummarizedExperiment and altExp
# Create TreeSE with altExp
tse <- mae[[1]]
altExp(tse, "exp2") <- mae[[2]]

# When mode = matrix, matrix is returned
result <- getExperimentCrossAssociation(tse, experiment2 = "exp2",
                                       abund_values1 = "rclr", abund_values2 = "counts",
                                       method = "pearson", mode = "matrix")

# Show first 5 entries
head(result, 5)

# testExperimentCorrelation returns also significances
# filter_self_correlations = TRUE filters self correlations
# With p_adj_threshold it is possible to filter those features that do not have
# any correlations that have p-value under threshold
result <- testExperimentCrossAssociation(tse, experiment2 = tse, method = "pearson",
                                       filter_self_correlations = TRUE,
                                       p_adj_threshold = 0.05)

# Show first 5 entries
head(result, 5)

# Also getExperimentCrossAssociation returns significances when
# test_significance = TRUE
# Warnings can be suppressed by using show_warnings = FALSE
result <- getExperimentCrossAssociation(mae[[1]], experiment2 = mae[[2]], method = "pearson",
                                       mode = "matrix", test_significance = TRUE,
                                       show_warnings = FALSE)

# Returned value is a list of matrices
names(result)

# Calculate Bray-Curtis dissimilarity between samples. If dataset includes
# paired samples, you can use paired = TRUE.
result <- getExperimentCrossAssociation(mae[[1]], mae[[2]], MARGIN = 2, paired = FALSE,
                                       association_FUN = vegan::vegdist, method = "bray")

# If experiments are equal and measure is symmetric (e.g., taxa1 vs taxa2 == taxa2 vs taxa1),
# it is possible to speed-up calculations by calculating association only for unique
# variable-pairs. Use "symmetric" to choose whether to measure association for only
# other half of of variable-pairs.
result <- getExperimentCrossAssociation(mae, experiment1 = "microbiome", experiment2 = "microbiome",
                                       abund_values1 = "counts", abund_values2 = "counts",
                                       symmetric = TRUE)

# For big data sets, calculation might take long. To make calculations quicker, you can take
# a random sample from data. In a complex biological problems, random sample
# can describe the data enough. Here our random sample is 30 % of whole data.
sample_size <- 0.3

```

```
tse_sub <- tse[ sample( seq_len( nrow(tse) ), sample_size * nrow(tse) ), ]
result <- testExperimentCrossAssociation(tse_sub)
```

---

getPrevalence

*Calculation prevalence information for features across samples*

---

## Description

These functions calculate the population prevalence for taxonomic ranks in a [SummarizedExperiment-class](#) object.

## Usage

```
getPrevalence(x, ...)

## S4 method for signature 'ANY'
getPrevalence(x, detection = 0, include_lowest = FALSE, sort = FALSE, ...)

## S4 method for signature 'SummarizedExperiment'
getPrevalence(x, abund_values = "counts", as_relative = TRUE, rank = NULL, ...)

getPrevalentTaxa(x, ...)

## S4 method for signature 'ANY'
getPrevalentTaxa(x, prevalence = 50/100, include_lowest = FALSE, ...)

## S4 method for signature 'SummarizedExperiment'
getPrevalentTaxa(
  x,
  rank = NULL,
  prevalence = 50/100,
  include_lowest = FALSE,
  ...
)

getRareTaxa(x, ...)

## S4 method for signature 'ANY'
getRareTaxa(x, prevalence = 50/100, include_lowest = FALSE, ...)

## S4 method for signature 'SummarizedExperiment'
getRareTaxa(x, rank = NULL, prevalence = 50/100, include_lowest = FALSE, ...)

subsetByPrevalentTaxa(x, ...)
```

```

## S4 method for signature 'SummarizedExperiment'
subsetByPrevalentTaxa(x, rank = NULL, ...)

subsetByRareTaxa(x, ...)

## S4 method for signature 'SummarizedExperiment'
subsetByRareTaxa(x, rank = NULL, ...)

getPrevalentAbundance(x, abund_values = "relabundance", ...)

## S4 method for signature 'ANY'
getPrevalentAbundance(x, abund_values = "relabundance", ...)

## S4 method for signature 'SummarizedExperiment'
getPrevalentAbundance(x, abund_values = "counts", ...)

agglomerateByPrevalence(x, ...)

## S4 method for signature 'SummarizedExperiment'
agglomerateByPrevalence(
  x,
  rank = taxonomyRanks(x)[1L],
  other_label = "Other",
  ...
)

```

### Arguments

x	a <a href="#">SummarizedExperiment</a> object
detection	Detection threshold for absence/presence. Either an absolute value compared directly to the values of x or a relative value between 0 and 1, if <code>as_relative = TRUE</code> .
include_lowest	logical scalar: Should the lower boundary of the detection and prevalence cutoffs be included? (default: FALSE)
sort	logical scalar: Should the result be sorted by prevalence? (default: FALSE)
abund_values	A single character value for selecting the <a href="#">assay</a> to use for prevalence calculation.
as_relative	logical scalar: Should the detection threshold be applied on compositional (relative) abundances? (default: TRUE)
rank, ...	additional arguments <ul style="list-style-type: none"> <li>• If <code>!is.null(rank)</code> arguments are passed on to <a href="#">agglomerateByRank</a>. See <a href="#">?agglomerateByRank</a> for more details.</li> <li>• for <code>getPrevalentTaxa</code>, <code>getRareTaxa</code>, <code>subsetByPrevalentTaxa</code> and <code>subsetByRareTaxa</code> additional parameters passed to <code>getPrevalence</code></li> <li>• for <code>getPrevalentAbundance</code> additional parameters passed to <code>getPrevalentTaxa</code></li> </ul>
prevalence	Prevalence threshold (in 0 to 1). The required prevalence is strictly greater by default. To include the limit, set <code>include_lowest</code> to TRUE.

`other_label` A single character valued used as the label for the summary of non-prevalent taxa. (default: `other_label = "Other"`)

### Details

`getPrevalence` calculates the relative frequency of samples that exceed the detection threshold. For `SummarizedExperiment` objects, the prevalence is calculated for the selected taxonomic rank, otherwise for the rows. The absolute population prevalence can be obtained by multiplying the prevalence by the number of samples (`ncol(x)`). If `as_relative = TRUE` the relative frequency (between 0 and 1) is used to check against the detection threshold.

The core abundance index from `getPrevalentAbundance` gives the relative proportion of the core species (in between 0 and 1). The core taxa are defined as those that exceed the given population prevalence threshold at the given detection level as set for `getPrevalentTaxa`.

`subsetPrevalentTaxa` and `subsetRareTaxa` return a subset of `x`. The subset includes the most prevalent or rare taxa that are calculated with `getPrevalentTaxa` or `getRareTaxa` respectively.

`getPrevalentTaxa` returns taxa that are more prevalent with the given detection threshold for the selected taxonomic rank.

`getRareTaxa` returns complement of `getPrevalentTaxa`.

### Value

`subsetPrevalentTaxa` and `subsetRareTaxa` return subset of `x`.

All other functions return a named vectors:

- `getPrevalence` returns a numeric vector with the names being set to either the row names of `x` or the names after agglomeration.
- `getPrevalentAbundance` returns a numeric vector with the names corresponding to the column name of `x` and include the joint abundance of prevalent taxa.
- `getPrevalentTaxa` and `getRareTaxa` return a character vector with only the names exceeding the threshold set by prevalence, if the rownames of `x` is set. Otherwise an integer vector is returned matching the rows in `x`.

---

isContaminant	<i>decontam functions</i>
---------------	---------------------------

---

## Description

The decontam functions `isContaminant` and `isNotContaminant` are made available for [SummarizedExperiment](#) objects.

## Usage

```

## S4 method for signature 'SummarizedExperiment'
isContaminant(
  seqtab,
  abund_values = "counts",
  name = "isContaminant",
  concentration = NULL,
  control = NULL,
  batch = NULL,
  threshold = 0.1,
  normalize = TRUE,
  detailed = TRUE,
  ...
)

## S4 method for signature 'SummarizedExperiment'
isNotContaminant(
  seqtab,
  abund_values = "counts",

```

```

    name = "isNotContaminant",
    control = NULL,
    threshold = 0.5,
    normalize = TRUE,
    detailed = FALSE,
    ...
)

addContaminantQC(x, name = "isContaminant", ...)

## S4 method for signature 'SummarizedExperiment'
addContaminantQC(x, name = "isContaminant", ...)

addNotContaminantQC(x, name = "isNotContaminant", ...)

## S4 method for signature 'SummarizedExperiment'
addNotContaminantQC(x, name = "isNotContaminant", ...)

```

### Arguments

seqtab, x	a <a href="#">SummarizedExperiment</a>
abund_values	A single character value for selecting the <a href="#">assay</a> to use.
name	A name for the column of the colData in which the contaminant information should be stored.
concentration	NULL or a single character value. Defining a column with numeric values from the colData to use as concentration information. (default: concentration = NULL)
control	NULL or a single character value. Defining a column with logical values from the colData to define control and non-control samples. (default: control = NULL)
batch	NULL or a single character value. Defining a column with values interpretable as a factor from the colData to use as batch information. (default: batch = NULL)
threshold	numeric scalar. See <a href="#">decontam:isContaminant</a> or <a href="#">decontam:isNotContaminant</a>
normalize, detailed	logical scalar. See <a href="#">decontam:isContaminant</a> or <a href="#">decontam:isNotContaminant</a>
...	<ul style="list-style-type: none"> <li>• for <a href="#">isContaminant/ isNotContaminant</a>: arguments passed on to <a href="#">decontam:isContaminant</a> or <a href="#">decontam:isNotContaminant</a></li> <li>• for <a href="#">addContaminantQC/addNotContaminantQC</a>: arguments passed on to <a href="#">isContaminant/ isNotContaminant</a></li> </ul>

### Value

for [isContaminant/ isNotContaminant](#) a `DataFrame` or for [addContaminantQC/addNotContaminantQC](#) a modified object of `class(x)`

**See Also**

[decontam:isContaminant](#), [decontam:isNotContaminant](#)

**Examples**

```
data(esophagus)
# setup of some mock data
colData(esophagus)$concentration <- c(1,2,3)
colData(esophagus)$control <- c(FALSE,FALSE,TRUE)

isContaminant(esophagus,
               method = "frequency",
               concentration = "concentration")
esophagus <- addContaminantQC(esophagus,
                              method = "frequency",
                              concentration = "concentration")

colData(esophagus)

isNotContaminant(esophagus, control = "control")
esophagus <- addNotContaminantQC(esophagus, control = "control")
colData(esophagus)
```

---

loadFromMetaphlan	<i>Import Metaphlan results to TreeSummarizedExperiment</i>
-------------------	---

---

**Description**

Import Metaphlan results to TreeSummarizedExperiment

**Arguments**

file	a single character value defining the file path of the Metaphlan file. The file must be in merged Metaphlan format.
sample_meta	a single character value defining the file path of the sample metadata file. The file must be in tsv format (default: sample_meta = NULL).
phy_tree	a single character value defining the file path of the phylogenetic tree. (default: phy_tree = NULL).
...	additional arguments: <ul style="list-style-type: none"> <li>• abund_values: A single character value for naming <a href="#">assay</a> (default: abund_values = "counts")</li> <li>• removeTaxaPrefixes: TRUE or FALSE: Should taxonomic prefixes be removed? (default: removeTaxaPrefixes = FALSE)</li> </ul>

**Details**

Import Metaphlan results. Input must be in merged Metaphlan format. Data is imported so that data at the lowest rank is imported as a TreeSE object. Data at higher rank is imported as a SE objects which are stored to altExp of TreeSE object.

**Value**

A [TreeSummarizedExperiment](#) object

**Author(s)**

Leo Lahti and Tuomas Borman. Contact: [microbiome.github.io](https://microbiome.github.io)

file_path <- system.file("extdata", "merged_abundance_table.txt", package = "mia")
# Import data
tse <- loadFromMetaphlan(file_path)
# Data at the lowest rank
tse
# Data at higher rank is stored in altExp
altExps(tse)
# Higher rank data is in SE format, for example, Phylum rank
altExp(tse, "Phylum")
```

---

loadFromMothur

*Import Mothur results as a SummarizedExperiment*

---

**Description**

This method creates a `SummarizedExperiment` object from Mothur files provided as input.

**Usage**

```
loadFromMothur(sharedFile, taxonomyFile = NULL, designFile = NULL)
```

**Arguments**

sharedFile	a single character value defining the file path of the feature table to be imported. The File has to be in shared file format as defined in Mothur documentation.
taxonomyFile	a single character value defining the file path of the taxonomy table to be imported. The File has to be in taxonomy file or constaxonomy file format as defined in Mothur documentation. (default: taxonomyFile = NULL).
designFile	a single character value defining the file path of the sample metadata to be imported. The File has to be in desing file format as defined in Mothur documentation. (default: designFile = NULL).

**Details**

Results exported from Mothur can be imported as a SummarizedExperiment using loadFromMothur. Except for the sharedFile, the other data types, taxonomyFile, and designFile, are optional, but are highly encouraged to be provided.

**Value**

A [SummarizedExperiment](#) object

**Author(s)**

Leo Lahti and Tuomas Borman. Contact: [microbiome.github.io](https://microbiome.github.io)

# Creates se object from files
se <- loadFromMothur(counts, taxa, meta)
# Convert SE to TreeSE
tse <- as(se, "TreeSummarizedExperiment")
```

tse

---

loadFromQIIME2      *Import QIIME2 results to TreeSummarizedExperiment*

---

## Description

Results exported from QIIME2 can be imported as a `TreeSummarizedExperiment` using `loadFromQIIME2`. Except for the `featureTableFile`, the other data types, `taxonomyTableFile`, `refSeqFile` and `phyTreeFile`, are optional, but are highly encouraged to be provided.

Import the QIIME2 artifacts to R.

## Usage

```
loadFromQIIME2(
  featureTableFile,
  taxonomyTableFile = NULL,
  sampleMetaFile = NULL,
  featureNamesAsRefSeq = TRUE,
  refSeqFile = NULL,
  phyTreeFile = NULL,
  ...
)

readQZA(file, temp = tempdir(), ...)
```

## Arguments

<code>featureTableFile</code>	a single character value defining the file path of the feature table to be imported.
<code>taxonomyTableFile</code>	a single character value defining the file path of the taxonomy table to be imported. (default: <code>taxonomyTableFile = NULL</code> ).
<code>sampleMetaFile</code>	a single character value defining the file path of the sample metadata to be imported. The file has to be in tsv format. (default: <code>sampleMetaFile = NULL</code> ).
<code>featureNamesAsRefSeq</code>	TRUE or FALSE: Should the feature names of the feature table be regarded as reference sequences? This setting will be disregarded, if <code>refSeqFile</code> is not NULL. If the feature names do not contain valid DNA characters only, the reference sequences will not be set.
<code>refSeqFile</code>	a single character value defining the file path of the reference sequences for each feature. (default: <code>refSeqFile = NULL</code> ).
<code>phyTreeFile</code>	a single character value defining the file path of the phylogenetic tree. (default: <code>phyTreeFile = NULL</code> ).

...	additional arguments: <ul style="list-style-type: none"> <li>temp: the temporary directory used for decompressing the data. (default: tempdir())</li> <li>removeTaxaPrefixes: TRUE or FALSE: Should taxonomic prefixes be removed? (default: removeTaxaPrefixes = FALSE)</li> </ul>
file	character, path of the input qza file. Only files in format of BIOMV210DirFmt (feature table), TSVTaxonomyDirectoryFormat (taxonomic table), NewickDirectoryFormat (phylogenetic tree ) and DNASequencesDirectoryFormat (representative sequences) are supported right now.
temp	character, a temporary directory in which the qza file will be decompressed to, default tempdir().

### Details

Both arguments featureNamesAsRefSeq and refSeqFile can be used to define reference sequences of features. featureNamesAsRefSeq is only taken into account, if refSeqFile is NULL. No reference sequences are tried to be created, if featureNameAsRefSeq is FALSE and refSeqFile is NULL.

### Value

A `TreeSummarizedExperiment` object

matrix object for feature table, `DataFrame` for taxonomic table, `ape::phylo` object for phylogenetic tree, `Biostrings::DNAStringSet` for representative sequences of taxa.

se

```

---

```
makePhyloseqFromTreeSummarizedExperiment
```

*Create a phyloseq object from a TreeSummarizedExperiment object*

---

## Description

This function creates a phyloseq object from a TreeSummarizedExperiment object. By using `abund_values`, it is possible to specify which table from assay is added to the phyloseq object.

## Usage

```

makePhyloseqFromTreeSummarizedExperiment(x, ...)

## S4 method for signature 'SummarizedExperiment'
makePhyloseqFromTreeSummarizedExperiment(x, abund_values = "counts")

## S4 method for signature 'TreeSummarizedExperiment'
makePhyloseqFromTreeSummarizedExperiment(x, ...)

```

### Arguments

x	a TreeSummarizedExperiment object
...	additional arguments
abund_values	A single character value for selecting the <a href="#">assay</a> to be included in the phyloseq object that is created. By default, it is counts table.

### Details

makePhyloseqFromTreeSummarizedExperiment is used for creating a phyloseq object from TreeSummarizedExperiment object.

### Value

An object of class Phyloseq object.

### Author(s)

Leo Lahti and Tuomas Borman. Contact: [microbiome.github.io](https://microbiome.github.io)

### Examples

```
# Get tse object
data(GlobalPatterns)
tse <- GlobalPatterns

# Create a phyloseq object from it
phy <- makePhyloseqFromTreeSummarizedExperiment(tse)
phy

# By default the chosen table is counts, but if there are other tables,
# they can be chosen with abund_values.

# Counts relative abundances table
tse <- transformCounts(tse, method = "relabundance")
phy2 <- makePhyloseqFromTreeSummarizedExperiment(tse, abund_values = "relabundance")
phy2
```

---

makeSummarizedExperimentFromBiom

*Loading a biom file*

---

### Description

For convenience a few functions are available to convert data from a 'biom' file or object into a [SummarizedExperiment](#)

**Usage**

```
loadFromBiom(file)

makeSummarizedExperimentFromBiom(obj)
```

**Arguments**

file	biom file location
obj	object of type <code>biom</code>

**Value**

An object of class `SummarizedExperiment`

**See Also**

[makeTreeSummarizedExperimentFromPhyloseq](#) [makeTreeSummarizedExperimentFromDADA2](#) [loadFromQIIME2](#)  
[loadFromMothur](#)

**Examples**

```
if(requireNamespace("biomformat")) {
  library(biomformat)
  # load from file
  rich_dense_file = system.file("extdata", "rich_dense_otu_table.biom",
                                package = "biomformat")
  se <- loadFromBiom(rich_dense_file)

  # load from object
  x1 <- biomformat::read_biom(rich_dense_file)
  se <- makeSummarizedExperimentFromBiom(x1)
  # Convert SE to TreeSE
  tse <- as(se, "TreeSummarizedExperiment")
  tse
}
```

---

```
makeTreeSummarizedExperimentFromDADA2
  Coerce 'DADA2' results to TreeSummarizedExperiment
```

---

**Description**

`makeTreeSummarizedExperimentFromDADA2` is a wrapper for the `mergePairs` function from the `dada2` package.

**Usage**

```
makeTreeSummarizedExperimentFromDADA2(...)
```

**Arguments**

... See mergePairs function for more details.

**Details**

A count matrix is constructed via makeSequenceTable(mergePairs(...)) and rownames are dynamically created as ASV(N) with N from 1 to nrow of the count tables. The colnames and rownames from the output of makeSequenceTable are stored as colnames and in the referenceSeq slot of the TreeSummarizedExperiment, respectively.

**Value**

An object of class TreeSummarizedExperiment

**See Also**

[makeTreeSummarizedExperimentFromPhyloseq](#) [makeSummarizedExperimentFromBiom](#) [loadFromQIIME2](#)  
[loadFromMothur](#)

**Examples**

```
if(requireNamespace("dada2")) {
  fnF <- system.file("extdata", "sam1F.fastq.gz", package="dada2")
  fnR = system.file("extdata", "sam1R.fastq.gz", package="dada2")
  dadaF <- dada2::dada(fnF, selfConsist=TRUE)
  dadaR <- dada2::dada(fnR, selfConsist=TRUE)

  tse <- makeTreeSummarizedExperimentFromDADA2(dadaF, fnF, dadaR, fnR)
  tse
}
```

---

```
makeTreeSummarizedExperimentFromPhyloseq
```

*Coerce a phyloseq object to a TreeSummarizedExperiment*

---

**Description**

makeTreeSummarizedExperimentFromPhyloseq converts phyloseq objects into TreeSummarizedExperiment objects.

**Usage**

```
makeTreeSummarizedExperimentFromPhyloseq(obj)
```

**Arguments**

obj a phyloseq object

**Details**

All data stored in a phyloseq object is transferred.

**Value**

An object of class TreeSummarizedExperiment

**See Also**

[makeSummarizedExperimentFromBiom](#) [makeTreeSummarizedExperimentFromDADA2](#) [loadFromQIIME2](#)  
[loadFromMothur](#)

**Examples**

```
if (requireNamespace("phyloseq")) {
  data(GlobalPatterns, package="phyloseq")
  makeTreeSummarizedExperimentFromPhyloseq(GlobalPatterns)
  data(enterotype, package="phyloseq")
  makeTreeSummarizedExperimentFromPhyloseq(enterotype)
  data(esophagus, package="phyloseq")
  makeTreeSummarizedExperimentFromPhyloseq(esophagus)
}
```

---

meltAssay

---

*Converting a [SummarizedExperiment](#) object into a long data.frame*

---

**Description**

meltAssay Converts a [SummarizedExperiment](#) object into a long data.frame which can be used for tidyverse-tools.

**Usage**

```
meltAssay(
  x,
  abund_values = "counts",
  add_row_data = NULL,
  add_col_data = NULL,
  feature_name = "FeatureID",
  sample_name = "SampleID",
  ...
)

## S4 method for signature 'SummarizedExperiment'
meltAssay(
  x,
  abund_values = "counts",
  add_row_data = NULL,
```

```

    add_col_data = NULL,
    feature_name = "FeatureID",
    sample_name = "SampleID",
    ...
  )

```

## Arguments

x	A numeric matrix or a <a href="#">SummarizedExperiment</a>
abund_values	a character value to select an <a href="#">assayNames</a>
add_row_data	NULL, TRUE or a character vector to select information from the rowData to add to the molten assay data. If add_row_data = NULL no data will be added, if add_row_data = TRUE all data will be added and if add_row_data is a character vector, it will be used to subset to given column names in rowData. (default: add_row_data = NULL)
add_col_data	NULL, TRUE or a character vector to select information from the colData to add to the molten assay data. If add_col_data = NULL no data will be added, if add_col_data = TRUE all data will be added and if add_col_data is a character vector, it will be used to subset to given column names in colData. (default: add_col_data = NULL)
feature_name	a character scalar to use as the output's name for the feature identifier. (default: feature_name = "FeatureID")
sample_name	a character scalar to use as the output's name for the sample identifier. (default: sample_name = "SampleID")
...	optional arguments: <ul style="list-style-type: none"> <li>• check_names A boolean value passed to data.frame function's check.name argument. Determines if sample names are checked that they are syntactically valid variable names and are not duplicated. If they are not, sample names are modified. (default: check_names = TRUE)</li> </ul>

## Details

If the colData contains a column "SampleID" or the rowData contains a column "FeatureID", they will be renamed to "SampleID\_col" and "FeatureID\_row", if row names or column names are set.

## Value

A tibble with the molten data. The assay values are given in a column named like the selected assay abund\_values. In addition, a column "FeatureID" will contain the rownames, if set, and analogously a column "SampleID" with the colnames, if set

## Author(s)

Sudarshan A. Shetty

**Examples**

```

data(GlobalPatterns)
molten_tse <- meltAssay(GlobalPatterns,
                        abund_values = "counts",
                        add_row_data = TRUE,
                        add_col_data = TRUE
                        )

molten_tse

```

merge-methods

*Merge a subset of the rows or columns of a SummarizedExperiment***Description**

mergeRows/mergeCols merge data on rows or columns of a SummarizedExperiment as defined by a factor alongside the chosen dimension. Metadata from the rowData or colData are retained as defined by archetype.

**Usage**

```

mergeRows(x, f, archetype = 1L, ...)

mergeCols(x, f, archetype = 1L, ...)

## S4 method for signature 'SummarizedExperiment'
mergeRows(x, f, archetype = 1L, ...)

## S4 method for signature 'SummarizedExperiment'
mergeCols(x, f, archetype = 1L, ...)

## S4 method for signature 'TreeSummarizedExperiment'
mergeRows(x, f, archetype = 1L, mergeTree = FALSE, mergeRefSeq = FALSE, ...)

## S4 method for signature 'TreeSummarizedExperiment'
mergeCols(x, f, archetype = 1L, mergeTree = FALSE, ...)

```

**Arguments**

x	a <a href="#">SummarizedExperiment</a> or a <a href="#">TreeSummarizedExperiment</a>
f	A factor for merging. Must be the same length as nrow(x)/ncol(x). Rows/Cols corresponding to the same level will be merged. If length(levels(f)) == nrow(x)/ncol(x), x will be returned unchanged.
archetype	Of each level of f, which element should be regarded as the archetype and metadata in the columns or rows kept, while merging? This can be single integer value or an integer vector of the same length as levels(f). (Default: archetype = 1L, which means the first element encountered per factor level will be kept)

...	optional arguments: <ul style="list-style-type: none"> <li>passed onto <a href="#">sumCountsAcrossFeatures</a>, except subset_row, subset_col</li> </ul>
mergeTree	TRUE or FALSE: should to rowTree() also be merged? (Default: mergeTree = FALSE)
mergeRefSeq	TRUE or FALSE: should a consensus sequence calculate? If set to FALSE, the result from archetype is returned; If set to TRUE the result from <a href="#">DECIPHER::ConsensusSequence</a> is returned. (Default: mergeRefSeq = FALSE)

## Details

[assay](#) are agglomerated, i.e.. summed up. Other than counts / absolute values might lead to meaningless values.

These functions are similar to [sumCountsAcrossFeatures](#). However, additional support for TreeSummarizedExperiment was added and science field agnostic names were used. In addition the archetype argument lets the user select how to preserve row or column data.

For merge data of assays the function from `scuttle` are used.

## Value

an object with the same class `x` with the specified entries merged into one entry in all relevant components.

## See Also

[sumCountsAcrossFeatures](#)

## Examples

```
data(esophagus)
esophagus
plot(rowTree(esophagus))
# get a factor for merging
f <- factor(regmatches(rownames(esophagus),
                        regexpr("^[0-9]*_[0-9]*", rownames(esophagus))))
merged <- mergeRows(esophagus, f)
plot(rowTree(merged))
#
data(GlobalPatterns)
GlobalPatterns
merged <- mergeCols(GlobalPatterns, colData(GlobalPatterns)$SampleType)
merged
```

---

mia-datasets

*mia datasets*

---

## Description

These datasets are conversions of the **phyloseq** datasets `GlobalPatterns`, `enterotype`, and `esophagus` into the `TreeSummarizedExperiment` data container.

`dmn_se` contains an example `SummarizedExperiment` derived from data in the **DirichletMultinomial** package. See `?calculatedDMN` for more details.

Global patterns of 16S rRNA diversity at a depth of millions of sequences per sample (2011)

This work compared the microbial communities from 25 environmental samples and three known “mock communities” at a an averag depth of 3.1 million reads per sample. Authors reproduced diversity patterns seen in many other published studies, while investigating technical issues/bias by applying the same techniques to simulated microbial communities of known composition. Many thanks to J. Gregory Caporaso for providing the OTU-clustered data files for inclusion in the **phyloseq** package, from which this data `TreeSummarizedExperiment` version was then converted.

The enterotype data of the human gut microbiome (Arumugam et al. 2011) includes taxonomic profiling for 280 fecal samples from 22 subjects based on shotgun DNA sequencing. The authors claimed that the data naturally clumps into three community-level clusters, or “enterotypes”, that are not immediately explained by sequencing technology or demographic features of the subjects. A later addendum (2014) the authors stated that enterotypes "should not be seen as discrete clusters, but as a way of stratifying samples to reduce complexity."

The esophagus data set from Pei et al. (2004) includes 3 samples from 3 human adults based on biopsies analysed with 16S rDNA PCR. The 16S rRNA sequence processing has been provided in the `mothur` wiki at the link below.

This data set from Turnbaugh et al. (2009) was used to introduce Dirichlet Multinomial Mixtures (DMM) for microbiota stratification by Holmes et al. (2012).

## Usage

```
data(GlobalPatterns)
```

```
data(enterotype)
```

```
data(esophagus)
```

```
data(dmn_se)
```

## Format

An object of class `TreeSummarizedExperiment` with 19216 rows and 26 columns.

An object of class `TreeSummarizedExperiment` with 553 rows and 280 columns.

An object of class `TreeSummarizedExperiment` with 58 rows and 3 columns.

An object of class `SummarizedExperiment` with 130 rows and 278 columns.

---

perSampleDominantTaxa *Get dominant taxa*

---

**Description**

These functions return information about the most dominant taxa in a [SummarizedExperiment](#) object.

**Usage**

```
perSampleDominantTaxa(x, abund_values = "counts", rank = NULL, ...)

## S4 method for signature 'SummarizedExperiment'
perSampleDominantTaxa(x, abund_values = "counts", rank = NULL, ...)

addPerSampleDominantTaxa(x, name = "dominant_taxa", ...)

## S4 method for signature 'SummarizedExperiment'
addPerSampleDominantTaxa(x, name = "dominant_taxa", ...)
```

**Arguments**

x	A <a href="#">SummarizedExperiment</a> object.
abund_values	A single character value for selecting the <a href="#">assay</a> to use for identifying dominant taxa.
rank	A single character defining a taxonomic rank. Must be a value of the output of <a href="#">taxonomyRanks()</a> .
...	Additional arguments passed on to <a href="#">agglomerateByRank()</a> when rank is specified.
name	A name for the column of the <a href="#">colData</a> where the dominant taxa will be stored in when using <a href="#">addPerSampleDominantTaxa</a> .

**Details**

[addPerSampleDominantTaxa](#) extracts the most abundant taxa in a [SummarizedExperiment](#) object, and stores the information in the [colData](#). It is a wrapper for [perSampleDominantTaxa](#).

With `rank` parameter, it is possible to agglomerate taxa based on taxonomic ranks. E.g. if 'Genus' rank is used, all abundances of same Genus are added together, and those families are returned. See [agglomerateByRank\(\)](#) for additional arguments to deal with missing values or special characters.

**Value**

[perSampleDominantTaxa](#) returns a named character vector `x` while [addPerSampleDominantTaxa](#) returns [SummarizedExperiment](#) with additional column in [colData](#) named `*name*`.

**Author(s)**

Leo Lahti, Tuomas Borman and Sudarshan A. Shetty.

**Examples**

```
data(GlobalPatterns)
x <- GlobalPatterns

# Finds the dominant taxa.
sim.dom <- perSampleDominantTaxa(x, rank="Genus")
```

```
# Add information to colData
x <- addPerSampleDominantTaxa(x, rank = "Genus", name="dominant_genera")
colData(x)
```

---

relabundance	<i>Getter / setter for relative abundance data</i>
--------------	--

---

### Description

relabundance is a getter/setter for relative abundance stored in the assay slot 'relabundance' of a [TreeSummarizedExperiment](#) object. This is a shortcut function for `assay(x, "relabundance")`.

### Usage

```
relabundance(x, ...)
```

```
relabundance(x) <- value
```

```
## S4 method for signature 'SummarizedExperiment'
```

```
relabundance(x)
```

```
## S4 replacement method for signature 'SummarizedExperiment'
```

```
relabundance(x) <- value
```

### Arguments

x	a <a href="#">TreeSummarizedExperiment</a> object
...	optional arguments not used currently.
value	a matrix to store as the the 'relabundance' assay

### Value

For relabundance the matrix stored with the name "relabundance".

### Examples

```
data(GlobalPatterns)
# Calculates relative abundances
GlobalPatterns <- relAbundanceCounts(GlobalPatterns)
# Fetches calculated relative abundances
head(relabundance(GlobalPatterns))
```

---

`runCCA`*Canonical Correspondance Analysis*

---

**Description**

These functions perform Canonical Correspondance Analysis on data stored in a `SummarizedExperiment`.

**Usage**

```
calculateCCA(x, ...)
```

```
runCCA(x, ...)
```

```
calculateRDA(x, ...)
```

```
runRDA(x, ...)
```

```
## S4 method for signature 'ANY'
```

```
calculateCCA(x, formula, variables, scale = TRUE, ...)
```

```
## S4 method for signature 'SummarizedExperiment'
```

```
calculateCCA(  
  x,  
  formula,  
  ...,  
  abund_values = exprs_values,  
  exprs_values = "counts"  
)
```

```
## S4 method for signature 'SingleCellExperiment'
```

```
runCCA(x, ..., altexp = NULL, name = "CCA")
```

```
## S4 method for signature 'ANY'
```

```
calculateRDA(x, formula, variables, scale = TRUE, ...)
```

```
## S4 method for signature 'SummarizedExperiment'
```

```
calculateRDA(  
  x,  
  formula,  
  ...,  
  abund_values = exprs_values,  
  exprs_values = "counts"  
)
```

```
## S4 method for signature 'SingleCellExperiment'
```

```
runRDA(x, ..., altexp = NULL, name = "RDA")
```

**Arguments**

x	For calculateCCA a numeric matrix with columns as samples or a <a href="#">SummarizedExperiment</a> . For runCCA a <a href="#">SingleCellExperiment</a> or a derived object.
...	additional arguments passed to <code>vegan::cca</code> or <code>vegan::rda</code> .
formula	If x is a <a href="#">SummarizedExperiment</a> a formula can be supplied. Based on the right-hand side of the given formula <code>colData</code> is subset to <code>variables</code> .
variables	a <code>data.frame</code> or an object coercible to one containing the variables to use. Can be missing, which turns the CCA analysis into a CA analysis. All variables are used. Please subset, if you want to consider only some of them.
scale	Logical scalar, should the expression values be standardized?
abund_values	a single character value for specifying which assay to use for calculation.
exprs_values	a single character value for specifying which assay to use for calculation. (Please use <code>abund_values</code> instead. At some point <code>exprs_values</code> will be disabled.)
altexp	String or integer scalar specifying an alternative experiment containing the input data.
name	String specifying the name to be used to store the result in the <code>reducedDims</code> of the output.

**Value**

For `calculateCCA` a matrix with samples as rows and CCA dimensions as columns

For `runCCA` a modified x with the results stored in `reducedDim` as the given name

**See Also**

For more details on the actual implementation see [cca](#) and [rda](#)

**Examples**

```
library(scater)
data(GlobalPatterns)
GlobalPatterns <- runCCA(GlobalPatterns, data ~ SampleType)
plotReducedDim(GlobalPatterns, "CCA", colour_by = "SampleType")

GlobalPatterns <- runRDA(GlobalPatterns, data ~ SampleType)
plotReducedDim(GlobalPatterns, "CCA", colour_by = "SampleType")
```

runDPCoA

*Calculation of Double Principal Correspondance analysis***Description**

Double Principal Correspondance analysis is made available via the `ade4` package in typical fashion. Results are stored in the `reducedDims` and are available for all the expected functions.

**Usage**

```

calculateDPCoA(x, y, ...)

## S4 method for signature 'ANY,ANY'
calculateDPCoA(
  x,
  y,
  ncomponents = 2,
  ntop = NULL,
  subset_row = NULL,
  scale = FALSE,
  transposed = FALSE
)

## S4 method for signature 'TreeSummarizedExperiment,missing'
calculateDPCoA(
  x,
  ...,
  abund_values = exprs_values,
  exprs_values = "counts",
  dimred = NULL,
  n_dimred = NULL
)

runDPCoA(x, ..., altexp = NULL, name = "DPCoA")

```

**Arguments**

<code>x</code>	For <code>calculateDPCoA</code> , a numeric matrix of expression values where rows are features and columns are cells. Alternatively, a <code>TreeSummarizedExperiment</code> containing such a matrix. For <code>runDPCoA</code> a <code>TreeSummarizedExperiment</code> containing the expression values as well as a <code>rowTree</code> to calculate <code>y</code> using <code>cophenetic.phylo</code> .
<code>y</code>	a dist or a symmetric matrix compatible with <code>ade4:dpcoa</code>
<code>...</code>	Currently not used.
<code>ncomponents</code>	Numeric scalar indicating the number of DPCoA dimensions to obtain.

<code>ntop</code>	Numeric scalar specifying the number of features with the highest variances to use for dimensionality reduction. Alternatively NULL, if all features should be used. (default: <code>ntop = NULL</code> )
<code>subset_row</code>	Vector specifying the subset of features to use for dimensionality reduction. This can be a character vector of row names, an integer vector of row indices or a logical vector.
<code>scale</code>	Logical scalar, should the expression values be standardized?
<code>transposed</code>	Logical scalar, is x transposed with cells in rows?
<code>abund_values</code>	a single character value for specifying which assay to use for calculation.
<code>exprs_values</code>	a single character value for specifying which assay to use for calculation. (Please use <code>abund_values</code> instead. At some point <code>exprs_values</code> will be disabled.)
<code>dimred</code>	String or integer scalar specifying the existing dimensionality reduction results to use.
<code>n_dimred</code>	Integer scalar or vector specifying the dimensions to use if <code>dimred</code> is specified.
<code>altexp</code>	String or integer scalar specifying an alternative experiment containing the input data.
<code>name</code>	String specifying the name to be used to store the result in the <code>reducedDims</code> of the output.

### Details

In addition to the reduced dimension on the features, the reduced dimension for samples are returned as well as `sample_red` attribute. e.g. `feature_weights` and `sample_weights` are returned as attributes as well.

### Value

For `calculateDPCoA` a matrix with samples as rows and CCA dimensions as columns

For `runDPCoA` a modified x with the results stored in `reducedDim` as the given name

### See Also

[plotReducedDim](#) [reducedDims](#)

### Examples

```
data(esophagus)
dpcoa <- calculateDPCoA(esophagus)
head(dpcoa)

esophagus <- runDPCoA(esophagus)
reducedDims(esophagus)

library(scater)
plotReducedDim(esophagus, "DPCoA")
```

runNMDS

*Perform non-metric MDS on sample-level data***Description**

Perform non-metric multi-dimensional scaling (nMDS) on samples, based on the data in a `SingleCellExperiment` object.

**Usage**

```
calculateNMDS(x, ...)

## S4 method for signature 'ANY'
calculateNMDS(
  x,
  FUN = vegdist,
  nmDSFUN = c("isoMDS", "monoMDS"),
  ncomponents = 2,
  ntop = 500,
  subset_row = NULL,
  scale = FALSE,
  transposed = FALSE,
  keep_dist = FALSE,
  ...
)

## S4 method for signature 'SummarizedExperiment'
calculateNMDS(
  x,
  ...,
  abund_values = exprs_values,
  exprs_values = "counts",
  FUN = vegdist
)

## S4 method for signature 'SingleCellExperiment'
calculateNMDS(
  x,
  ...,
  abund_values = exprs_values,
  exprs_values = "counts",
  dimred = NULL,
  n_dimred = NULL,
  FUN = vegdist
)

runNMDS(x, ..., altexp = NULL, name = "NMDS")
```

```
plotNMDS(x, ..., ncomponents = 2)
```

### Arguments

x	For calculateNMDS, a numeric matrix of expression values where rows are features and columns are cells. Alternatively, a TreeSummarizedExperiment containing such a matrix. For runNMDS a <a href="#">SingleCellExperiment</a>
...	additional arguments to pass to FUN and nmdsFUN.
FUN	a function or character value with a function name returning a <a href="#">dist</a> object
nmdsFUN	a character value to choose the scaling implementation, either “isoMDS” for <a href="#">MASS::isoMDS</a> or “monoMDS” for <a href="#">vegan::monoMDS</a>
ncomponents	Numeric scalar indicating the number of NMDS dimensions to obtain.
ntop	Numeric scalar specifying the number of features with the highest variances to use for dimensionality reduction.
subset_row	Vector specifying the subset of features to use for dimensionality reduction. This can be a character vector of row names, an integer vector of row indices or a logical vector.
scale	Logical scalar, should the expression values be standardized?
transposed	Logical scalar, is x transposed with cells in rows?
keep_dist	Logical scalar indicating whether the dist object calculated by FUN should be stored as ‘dist’ attribute of the matrix returned/stored by calculateNMDS/runNMDS.
abund_values	a single character value for specifying which assay to use for calculation.
exprs_values	a single character value for specifying which assay to use for calculation. (Please use abund_values instead. At some point exprs_values will be disabled.)
dimred	String or integer scalar specifying the existing dimensionality reduction results to use.
n_dimred	Integer scalar or vector specifying the dimensions to use if dimred is specified.
altexp	String or integer scalar specifying an alternative experiment containing the input data.
name	String specifying the name to be used to store the result in the reducedDims of the output.

### Details

Either [MASS::isoMDS](#) or [vegan::monoMDS](#) are used internally to compute the NMDS components. If you supply a custom FUN, make sure that the arguments of FUN and nmdsFUN do not collide.

### Value

For calculateNMDS, a matrix is returned containing the MDS coordinates for each sample (row) and dimension (column).

**Author(s)**

Felix Ernst

**See Also**

[MASS::isoMDS](#), [vegan::monoMDS](#) for NMDS component calculation.  
[plotMDS](#), to quickly visualize the results.

**Examples**

```
# generate some example data
mat <- matrix(1:60, nrow = 6)
df <- DataFrame(n = c(1:6))
tse <- TreeSummarizedExperiment(assays = list(counts = mat),
                                rowData = df)

#
calculateNMDS(tse)

#
data(esophagus)
esophagus <- runNMDS(esophagus, FUN = vegan::vegdist, name = "BC")
esophagus <- runNMDS(esophagus, FUN = vegan::vegdist, name = "euclidean",
                    method = "euclidean")
reducedDims(esophagus)
```

---

splitByRanks

*Split/Unsplit a SingleCellExperiment by taxonomic ranks*

---

**Description**

splitByRanks takes a SummarizedExperiment, splits it along the taxonomic ranks, aggregates the data per rank, converts the input to a SingleCellExperiment objects and stores the aggregated data as alternative experiments.

**Usage**

```
splitByRanks(x, ...)
```

## S4 method for signature 'SummarizedExperiment'

```
splitByRanks(x, ranks = taxonomyRanks(x), na.rm = TRUE, ...)
```

## S4 method for signature 'SingleCellExperiment'

```
splitByRanks(x, ranks = taxonomyRanks(x), na.rm = TRUE, ...)
```

## S4 method for signature 'TreeSummarizedExperiment'

```
splitByRanks(x, ranks = taxonomyRanks(x), na.rm = TRUE, ...)
```

```
unsplitByRanks(x, ...)
```

```
## S4 method for signature 'SingleCellExperiment'
unsplitByRanks(x, ranks = taxonomyRanks(x), keep_reducedDims = FALSE, ...)

## S4 method for signature 'TreeSummarizedExperiment'
unsplitByRanks(x, ranks = taxonomyRanks(x), keep_reducedDims = FALSE, ...)
```

## Arguments

x	a <a href="#">SummarizedExperiment</a> object
...	arguments passed to <a href="#">agglomerateByRank</a> function for <a href="#">SummarizedExperiment</a> objects and other functions. See <a href="#">agglomerateByRank</a> for more details.
ranks	a character vector defining taxonomic ranks. Must all be values of <a href="#">taxonomyRanks()</a> function.
na.rm	TRUE or FALSE: Should taxa with an empty rank be removed? Use it with caution, since results with NA on the selected rank will be dropped. This setting can be tweaked by defining <code>empty.fields</code> to your needs. (default: <code>na.rm = TRUE</code> )
keep_reducedDims	TRUE or FALSE: Should the <code>reducedDims(x)</code> be transferred to the result? Please note, that this breaks the link between the data used to calculate the reduced dims. (default: <code>keep_reducedDims = FALSE</code> )

## Details

`unsplitByRanks` takes these alternative experiments and flattens them again into a single [SummarizedExperiment](#).

`splitByRanks` will use by default all available taxonomic ranks, but this can be controlled by setting `ranks` manually. NA values are removed by default, since they would not make sense, if the result should be used for `unsplitByRanks` at some point. The input data remains unchanged in the returned [SingleCellExperiment](#) objects.

`unsplitByRanks` will remove any NA value on each taxonomic rank so that no ambiguous data is created. In addition, a column `taxonomicLevel` is created or overwritten in the `rowData` to specify from which alternative experiment this originates from. This can also be used for [splitAltExps](#) to split the result along the same factor again. The input data from the base objects is not returned, only the data from the `altExp()`. Be aware that changes to `rowData` of the base object are not returned, whereas only the `colData` of the base object is kept.

## Value

For `splitByRanks`: x, with objects of x agglomerated for selected ranks as `altExps`.

For `unsplitByRanks`: x, with `rowData` and assay data replaced by the unsplit data. `colData` of x is kept as well and any existing `rowTree` is dropped as well, since existing `rowLinks` are not valid anymore.

## See Also

**Examples**

```

data(GlobalPatterns)
# print the available taxonomic ranks
taxonomyRanks(GlobalPatterns)

# splitByRanks
altExps(GlobalPatterns) <- splitByRanks(GlobalPatterns)
altExps(GlobalPatterns)
altExp(GlobalPatterns,"Kingdom")
altExp(GlobalPatterns,"Species")

# unsplitByRanks
x <- unsplitByRanks(GlobalPatterns)
x

```

---

subsampleCounts	<i>Subsample Counts</i>
-----------------	-------------------------

---

**Description**

subsampleCounts will randomly subsample counts in SummarizedExperiment and return the a modified object in which each sample has same number of total observations/counts/reads.

**Usage**

```

subsampleCounts(
  x,
  abund_values = "counts",
  min_size = min(colSums2(assay(x))),
  seed = runif(1, 0, .Machine$integer.max),
  replace = TRUE,
  name = "subsampled",
  verbose = TRUE,
  ...
)

## S4 method for signature 'SummarizedExperiment'
subsampleCounts(
  x,
  abund_values = "counts",
  min_size = min(colSums2(assay(x))),
  seed = runif(1, 0, .Machine$integer.max),
  replace = TRUE,
  name = "subsampled",
  verbose = TRUE,
  ...
)

```

**Arguments**

x	A SummarizedExperiment object.
abund_values	A single character value for selecting the SummarizedExperiment assay used for random subsampling. Only counts are useful and other transformed data as input will give meaningless output.
min_size	A single integer value equal to the number of counts being simulated this can equal to lowest number of total counts found in a sample or a user specified number.
seed	A random number seed for reproducibility of sampling.
replace	Logical Default is TRUE. The default is with replacement (replace=TRUE). See <a href="#">phyloseq::rarefy_even_depth</a> for details on implications of this parameter.
name	A single character value specifying the name of transformed abundance table.
verbose	Logical Default is TRUE. When TRUE an additional message about the random number used is printed.
...	additional arguments not used

**Details**

Although the subsampling approach is highly debated in microbiome research, we include the `subsampleCounts` function because there may be some instances where it can be useful. Note that the output of `subsampleCounts` is not the equivalent as the input and any result have to be verified with the original dataset.

**Value**

`subsampleCounts` return x with subsampled data.

**Author(s)**

Sudarshan A. Shetty and Felix G.M. Ernst

subsetSamples

*Subset functions*

---

### Description

To make a transition from phyloseq easier, the subsetSamples and subsetFeatures functions are implemented. To avoid name clashes they are named differently.

### Usage

```
subsetSamples(x, ...)

subsetFeatures(x, ...)

subsetTaxa(x, ...)

## S4 method for signature 'SummarizedExperiment'
subsetSamples(x, ...)

## S4 method for signature 'SummarizedExperiment'
subsetFeatures(x, ...)

## S4 method for signature 'SummarizedExperiment'
subsetTaxa(x, ...)
```

### Arguments

x                    a [SummarizedExperiment](#) object  
...                   See [subset](#). drop is not supported.

### Details

However, the use of these functions is discouraged since subsetting using `[` works on both dimension at the same time, is more flexible and is used throughout R to subset data with two or more dimension. Therefore, these functions will be removed in Bioconductor release 3.15 (April, 2022).

### Value

A subset of x

**Examples**

```
data(GlobalPatterns)
subsetSamples(GlobalPatterns, colData(GlobalPatterns)$SampleType == "Soil")
# Vector that is used to specify subset must not include NAs
subsetFeatures(GlobalPatterns, rowData(GlobalPatterns)$Phylum == "Actinobacteria" &
  !is.na(rowData(GlobalPatterns)$Phylum))
```

---

summaries

*Summarizing microbiome data*

---

**Description**

To query a SummarizedExperiment for interesting features, several functions are available.

**Usage**

```
getTopTaxa(
  x,
  top = 5L,
  method = c("mean", "sum", "median"),
  abund_values = "counts",
  na.rm = TRUE,
  ...
)

## S4 method for signature 'SummarizedExperiment'
getTopTaxa(
  x,
  top = 5L,
  method = c("mean", "sum", "median", "prevalence"),
  abund_values = "counts",
  na.rm = TRUE,
  ...
)

getUniqueTaxa(x, ...)

## S4 method for signature 'SummarizedExperiment'
getUniqueTaxa(x, rank = NULL, ...)

countDominantTaxa(x, group = NULL, ...)

## S4 method for signature 'SummarizedExperiment'
countDominantTaxa(x, group = NULL, ...)

## S4 method for signature 'SummarizedExperiment'
summary(object, abund_values = "counts")
```

**Arguments**

x	A <a href="#">SummarizedExperiment</a> object.
top	Numeric value, how many top taxa to return. Default return top five taxa.
method	Specify the method to determine top taxa. Either sum, mean, median or prevalence. Default is 'mean'.
abund_values	a character value to select an <a href="#">assayNames</a> By default it expects count data.
na.rm	For <code>getTopTaxa</code> logical argument for calculation method specified to argument method. Default is TRUE.
...	Additional arguments passed on to <code>aggregateByRank()</code> when rank is specified for <code>countDominantTaxa</code> .
rank	A single character defining a taxonomic rank. Must be a value of the output of <code>taxonomyRanks()</code> .
group	With group, it is possible to group the observations in an overview. Must be one of the column names of <code>colData</code> .
object	A <a href="#">SummarizedExperiment</a> object.

**Details**

The `getTopTaxa` extracts the most top abundant “FeatureID”s in a [SummarizedExperiment](#) object.

The `getUniqueTaxa` is a basic function to access different taxa at a particular taxonomic rank.

`countDominantTaxa` returns information about most dominant taxa in a tibble. Information includes their absolute and relative abundances in whole data set.

The summary will return a summary of counts for all samples and features in [SummarizedExperiment](#) object.

**Value**

The `getTopTaxa` returns a vector of the most top abundant “FeatureID”s

The `getUniqueTaxa` returns a vector of unique taxa present at a particular rank

The `countDominantTaxa` returns an overview in a tibble. It contains dominant taxa in a column named `*name*` and its abundance in the data set.

The summary returns a list with two tibbles

taxonomy-methods

*Functions for accessing taxonomic data stored in rowData.*

---

## Description

These function work on data present in rowData and define a way to represent taxonomic data alongside the features of a SummarizedExperiment.

## Usage

TAXONOMY\_RANKS

```
taxonomyRanks(x)

## S4 method for signature 'SummarizedExperiment'
taxonomyRanks(x)

taxonomyRankEmpty(
  x,
  rank = taxonomyRanks(x)[1L],
  empty.fields = c(NA, "", " ", "\t", "-", "_")
)

## S4 method for signature 'SummarizedExperiment'
taxonomyRankEmpty(
  x,
  rank = taxonomyRanks(x)[1],
  empty.fields = c(NA, "", " ", "\t", "-", "_")
)

checkTaxonomy(x, ...)

## S4 method for signature 'SummarizedExperiment'
checkTaxonomy(x)

getTaxonomyLabels(x, ...)

## S4 method for signature 'SummarizedExperiment'
getTaxonomyLabels(
  x,
  empty.fields = c(NA, "", " ", "\t", "-", "_"),
  with_rank = FALSE,
  make_unique = TRUE,
  resolve_loops = FALSE
)

taxonomyTree(x, ...)

## S4 method for signature 'SummarizedExperiment'
taxonomyTree(x)

addTaxonomyTree(x, ...)

## S4 method for signature 'SummarizedExperiment'
addTaxonomyTree(x)

mapTaxonomy(x, ...)

## S4 method for signature 'SummarizedExperiment'
mapTaxonomy(x, taxa = NULL, from = NULL, to = NULL, use_grep1 = FALSE)
```

IdTaxaToDataFrame(from)

### Arguments

x	a <a href="#">SummarizedExperiment</a> object
rank	a single character defining a taxonomic rank. Must be a value of <code>taxonomyRanks()</code> function.
empty.fields	a character value defining, which values should be regarded as empty. (Default: <code>c(NA, "", " ", "\t")</code> ). They will be removed if <code>na.rm = TRUE</code> before agglomeration.
...	optional arguments not used currently.
with_rank	TRUE or FALSE: Should the level be add as a suffix? For example: "Phylum:Crenarchaeota" (default: <code>with_rank = FALSE</code> )
make_unique	TRUE or FALSE: Should the labels be made unique, if there are any duplicates? (default: <code>make_unique = TRUE</code> )
resolve_loops	TRUE or FALSE: Should <code>resolveLoops</code> be applied to the taxonomic data? Please note that has only an effect, if the data is unique. (default: <code>resolve_loops = TRUE</code> )
taxa	a character vector, which is used for subsetting the taxonomic information. If no information is found, NULL is returned for the individual element. (default: NULL)
from	<ul style="list-style-type: none"> <li>• For <code>mapTaxonomy</code>: a scalar character value, which must be a valid taxonomic rank. (default: NULL)</li> <li>• otherwise a <code>Taxa</code> object as returned by <a href="#">IdTaxa</a></li> </ul>
to	a scalar character value, which must be a valid taxonomic rank. (default: NULL)
use_grep1	TRUE or FALSE: should pattern matching via <code>grep1</code> be used? Otherwise literal matching is used. (default: FALSE)

### Format

a character vector of length 8 containing the taxonomy ranks recognized. In functions this is used as case insensitive.

### Details

`taxonomyRanks` returns, which columns of `rowData(x)` are regarded as columns containing taxonomic information.

`taxonomyRankEmpty` checks, if a selected rank is empty of information.

`checkTaxonomy` checks, if taxonomy information is valid and whether it contains any problems. This is a soft test, which reports some diagnostic and might mature into a data validator used upon object creation.

`getTaxonomyLabels` generates a character vector per row consisting of the lowest taxonomic information possible. If data from different levels, is to be mixed, the taxonomic level is prepended by default.

taxonomyTree generates a phylo tree object from the available taxonomic information. Internally it uses [toTree](#) and [resolveLoop](#) to sanitize data if needed.

IdTaxaToDataFrame extracts taxonomic results from results of [IdTaxa](#).

mapTaxonomy maps the given features (taxonomic groups; taxa) to the specified taxonomic level (to argument) in rowData of the SummarizedExperiment data object (i.e. `rowData(x)[, taxonomyRanks(x)]`). If the argument to is not provided, then all matching taxonomy rows in rowData will be returned. This function allows handy conversions between different

Taxonomic information from the IdTaxa function of DECIPHER package are returned as a special class. With `as(taxa, "DataFrame")` the information can be easily converted to a DataFrame compatible with storing the taxonomic information a rowData. Please note that the assigned confidence information are returned as metadata and can be accessed using `metadata(df)$confidence`.

### Value

- taxonomyRanks: a character vector with all the taxonomic ranks found in `colnames(rowData(x))`
- taxonomyRankEmpty: a logical value
- mapTaxonomy: a list per element of taxa. Each element is either a DataFrame, a character or NULL. If all character results have the length of one, a single character vector is returned.

```
data(GlobalPatterns)
GlobalPatterns
taxonomyRanks(GlobalPatterns)

checkTaxonomy(GlobalPatterns)

table(taxonomyRankEmpty(GlobalPatterns, "Kingdom"))
table(taxonomyRankEmpty(GlobalPatterns, "Species"))

getTaxonomyLabels(GlobalPatterns[1:20,])

# mapTaxonomy
## returns the unique taxonomic information
mapTaxonomy(GlobalPatterns)
# returns specific unique taxonomic information
mapTaxonomy(GlobalPatterns, taxa = "Escherichia")
# returns information on a single output
mapTaxonomy(GlobalPatterns, taxa = "Escherichia", to="Family")

# adding a rowTree() based on the available taxonomic information. Please
# note that any tree already stored in rowTree() will be overwritten.
x <- GlobalPatterns
x <- addTaxonomyTree(x)
x
```

---

transformCounts	<i>Transform Counts</i>
-----------------	-------------------------

---

## Description

These functions provide a variety of options for transforming abundance data. By using these functions, transformed table is calculated and stored in assay. transformSamples does the transformation sample-wise, i.e., column-wise. It is alias for transformCounts. transformFeatures does the transformation feature-wise, i.e., row-wise. ZTransform is a shortcut for Z-transformation. relAbundanceCounts is a shortcut for fetching relative abundance table.

## Usage

```
transformSamples(  
  x,  
  abund_values = "counts",  
  method = c("clr", "rclr", "hellinger", "log10", "pa", "rank", "relabundance"),  
  name = method,  
  pseudocount = FALSE,  
  threshold = 0  
)  
  
## S4 method for signature 'SummarizedExperiment'  
transformSamples(  
  x,  
  abund_values = "counts",  
  method = c("clr", "rclr", "hellinger", "log10", "pa", "rank", "relabundance"),  
  name = method,  
  pseudocount = FALSE,  
  threshold = 0  
)  
  
transformCounts(  
  x,  
  abund_values = "counts",  
  method = c("clr", "rclr", "hellinger", "log10", "pa", "rank", "relabundance"),  
  name = method,  
  pseudocount = FALSE,  
  threshold = 0  
)  
  
## S4 method for signature 'SummarizedExperiment'  
transformCounts(  
  x,  
  abund_values = "counts",  
  method = c("clr", "rclr", "hellinger", "log10", "pa", "rank", "relabundance"),  
  name = method,
```

```

    pseudocount = FALSE,
    threshold = 0
  )

transformFeatures(
  x,
  abund_values = "counts",
  method = c("log10", "pa", "z"),
  name = method,
  pseudocount = FALSE,
  threshold = 0
)

## S4 method for signature 'SummarizedExperiment'
transformFeatures(
  x,
  abund_values = "counts",
  method = c("log10", "pa", "z"),
  name = method,
  pseudocount = FALSE,
  threshold = 0
)

ZTransform(x, ...)

## S4 method for signature 'SummarizedExperiment'
ZTransform(x, ...)

relAbundanceCounts(x, ...)

## S4 method for signature 'SummarizedExperiment'
relAbundanceCounts(x, ...)

```

### Arguments

x	A <a href="#">SummarizedExperiment</a> object.
abund_values	A single character value for selecting the <a href="#">assay</a> to be transformed.
method	A single character value for selecting the transformation method.
name	A single character value specifying the name of transformed abundance table.
pseudocount	FALSE or numeric value deciding whether pseudocount is added. Numerical value specifies the value of pseudocount. (Only used for methods <code>method = "clr"</code> , <code>method = "hellinger"</code> , or <code>method = "log10"</code> )
threshold	A numeric value for setting threshold for pa transformation. By default it is 0. (Only used for <code>method = "pa"</code> )
...	additional arguments

## Details

transformCounts or transformSamples and transformFeatures applies transformation to abundance table. Provided transformation methods include:

- 'clr' Centered log ratio (clr) transformation can be used for reducing the skewness of data and for centering it. (See e.g. Gloor et al. 2017.)

$$clr = \log_{10} \frac{x_r}{g(x_r)} = \log_{10} x_r - \log_{10} g$$

where  $x_r$  is a single relative value,  $g(x_r)$  is geometric mean of sample-wide relative values, and  $\mu_r$  is arithmetic mean of sample-wide relative values".

- 'rclr' rclr or robust clr is similar to regular clr. Problem of regular clr is that logarithmic transformations lead to undefined values when zeros are present in the data. In rclr, values are divided by geometric mean of observed taxa and zero values are not taken into account. Zero values will stay as zeroes.

Because of high-dimensionality of data, rclr's geometric mean of observed taxa is a good approximation to the true geometric mean. (See e.g. Martino et al. 2019.)

$$rclr = \log_{10} \frac{x_r}{g(x_r > 0)}$$

where  $x_r$  is a single relative value, and  $g(x_r > 0)$  is geometric mean of sample-wide relative values that are over 0".

- 'hellinger' Hellinger transformation can be used to reduce the impact of extreme data points. It can be utilize for clustering or ordination analysis. (See e.g. Legendre & Gallagher 2001.)

$$hellinger = \sqrt{\frac{x}{x_{tot}}}$$

where  $x$  is a single value and  $x_{tot}$  is the sum of all values

- 'log10' log10 transformation can be used for reducing the skewness of the data.

$$\log_{10} = \log_{10} x$$

where  $x$  is a single value of data.

- 'pa' Transforms table to presence/absence table. All abundances higher than  $\epsilon$  are transformed to 1 (present), otherwise 0 (absent). By default, threshold is 0.
- 'rank' Rank returns ranks of taxa. For each sample, the least abundant taxa get lower value and more abundant taxa bigger value. The implementation is based on the colRanks function with ties.method="first".
- 'relabundance' Transforms abundances to relative. Generally, all microbiome data are compositional. That is, e.g., because all measuring instruments have their capacity limits. To make results comparable with other results, values must be relative. (See e.g. Gloor et al. 2017.)

$$relabundance = \frac{x}{x_{tot}}$$

where  $x$  is a single value and  $x_{tot}$  is the sum of all values.

- 'z' Z-transformation, Z score transformation, or Z-standardization normalizes the data by shifting (to mean  $\mu$ ) and scaling (to standard deviation  $\sigma$ ). Z-transformation can be done with function `ZTransform`. It is done per rows (features / taxa), unlike most other transformations. This is often preceded by `log10p` or `clr` transformation. In other words, single value is standardized with respect of feature's values.

$$z = \frac{x - \mu}{\sigma}$$

where  $x$  is a single value,  $\mu$  is the mean of the feature, and  $\sigma$  is the standard deviation of the feature.

### Value

`transformCounts`, `transformSamples`, `transformFeatures`, `relAbundanceCounts`, and `ZTransform` return  $x$  with additional, transformed abundance table named `name` in the [assay](#).

### Examples

```
data(esophagus)
x <- esophagus

# By specifying, it is possible to apply different transformations, e.g. clr transformation.
# Pseudocount can be added by specifying 'pseudocount'.
x <- transformSamples(x, method="clr", pseudocount=1)
head(assay(x, "clr"))

# Also, the target of transformation
# can be specified with "abund_values".
x <- transformSamples(x, method="relabundance")
x <- transformSamples(x, method="clr", abund_values="relabundance",
  pseudocount = min(assay(x, "relabundance")[assay(x, "relabundance")>0]))
x2 <- transformSamples(x, method="clr", abund_values="counts", pseudocount = 1)
head(assay(x, "clr"))

# Different pseudocounts used by default for counts and relative abundances
x <- transformSamples(x, method="relabundance")
```

```
mat <- assay(x, "relabundance");
pseudonumber <- min(mat[mat>0])
x <- transformSamples(x, method="clr", abund_values = "relabundance", pseudocount=pseudonumber)
x <- transformSamples(x, method="clr", abund_values = "counts", pseudocount=1)

# Name of the stored table can be specified.
x <- transformSamples(x, method="hellinger", name="test")
head(assay(x, "test"))

# pa returns presence absence table. With 'threshold', it is possible to set the
# threshold to a desired level. By default, it is 0.
x <- transformSamples(x, method="pa", threshold=35)
head(assay(x, "pa"))

# rank returns ranks of taxa. It is calculated column-wise, i.e., per sample
# and using the ties.method="first" from the colRanks function
x <- transformSamples(x, method="rank")
head(assay(x, "rank"))

# transformCounts is an alias for transformSamples
x <- transformCounts(x, method="relabundance", name="test2")
head(assay(x, "test2"))

# In order to use other ranking variants, modify the chosen assay directly:
assay(x, "rank_average", withDimnames = FALSE) <- colRanks(assay(x, "counts"),
                                                         ties.method="average",
                                                         preserveShape = TRUE)

# If you want to do the transformation for features, you can do that by using
x <- transformFeatures(x, method="log10", name="log10_features", pseudocount = 1)
head(assay(x, "log10_features"))

# Z-transform can be done for features by using shortcut function
x <- ZTransform(x)
head(assay(x, "z"))

# For visualization purposes it is sometimes done by applying CLR for samples,
# followed by Z transform for taxa
x <- ZTransform(transformCounts(x, method="clr", abund_values = "counts", pseudocount = 1))

# Relative abundances can be also calculated with the dedicated
# relAbundanceCounts function.
x <- relAbundanceCounts(x)
head(assay(x, "relabundance"))
```
